P R E F A C E.

THIS Volume contains the observations made with the Transit and Mural Circle in 1849, 1850, and 1851, and the Occultations of Fixed Stars by the Moon, the observations of Planets and Comets made with the Northumberland Equatorial in the same interval being reserved for separate publication.

The Meridian Observations were continued with but slight interruptions through the three years, and were almost all taken by Mr Breen and Mr Todd, who observed by turns with both instruments. Occasional observations were taken by myself, and in the autumn of 1849 some observations, both with the Transit and the Mural Circle, were taken by R. C. Carrington, Esq., who has since at the Durham Observatory, and more recently at his own Observatory at Redhill, performed good service in the field of astronomical science. I am also indebted to Mr Carrington for assistance in the calculations. Some of the transits of 1851 were taken by Mr John William Breen, brother of the Senior Assistant, to whom I gave permission to observe for the sake of practice.

The major part of the observations of the three years are directed towards the exact determination of the places of stars. In 1849 I commenced a series of observations of stars to the ninth magnitude inclusive, contained within a zone extending 5° on each side of the Ecliptic, the stars in this portion of the heavens being likely to be useful for comparison in Equatorial observations of the Minor Planets. At first it was intended to include in the series by independent observation all stars to the ninth magnitude contained within the zone, but this scheme being found to be too large for the personal force of the Observatory, the observations were confined to stars found in Weisse's Reduction of Bessel's Zones, and in the British Association Reduction of Lalande's *Histoire C  leste*, from which a working Catalogue of about 8000 stars was formed. This series of observations has already served to correct a considerable number of errors in Catalogues.

The observations of 1849 include some of the Minor Planets and Neptune. In the two following years observations of the Sun, and the Moon and Moon-culminating stars, were added, the former as being fundamental, and the latter to serve for the determination of Longitudes, and because the Moon-culminating stars are many of them contained in the above-mentioned Ecliptic Zone. All the observations of the Minor Planets are compared with calculated places, and if no Ephemeris was available for the purpose, the places were directly computed from Elements. This was done, not with the view of furnishing data for correcting the Theories of those bodies, but to give the means of judging of the value of each observation, and to indicate any that are anomalous, and also in some cases to decide whether the object observed was really the Planet, or a star mistaken for it.

All the observations have been completely reduced with the strictest attention to accuracy, and the calculations have all been carefully examined. The amount of calculation has necessarily been very large, both on account of the great number of the stars that were observed, especially in 1849, and the length of the calculations required for deducing theoretical places of the Minor Planets from the elements of their orbits. To these causes the long delay of the publication of this Volume is to be attributed.

J. CHALLIS.

ERRATA.

IN VOLUME XVII.

Pp. 324, 329 and 337. The minutes of N.P.D. of the star of R.A. $5^h.11^m.36^s$ observed Dec. 4, 1848, should be 19 instead of 20.

IN THE PRESENT VOLUME.

- p. xxiv, line 3 from the Table. *For* $+0''.41$ more southward, *read* $0''.41$ more northward.
- p. 5, Feb. 15. The concluded transit and apparent R.A. of \times N.P.D. $44^\circ.27'$ are 1^m too great.
- p. 5, Feb. 15. *For* \times N.P.D. $44^\circ.32'$ *read* \times N.P.D. $44^\circ.26'$.
- p. 7, Feb. 19 and 22. *For* \times N.P.D. $84^\circ.56'$ *read* \times N.P.D. $84^\circ.52'$.
- p. 9, March 17. The correction $+0''.47$ was applied to the observation of Polaris for form of the pivots instead of $-0''.49$. It has not been thought worth while to alter the observations affected by this mistake.
- p. 14, June 8. *For* Bessel xiv. 439 *read* Bessel xiv. 441.
- p. 18, July 12, 16 and 21. *For* H. C. 32493 *read* H. C. 32486.
- p. 25—39, in the space below the columns. *For* of *read* from, and *for* from *read* to, as in the other parts of the Volume.
- p. 44, last column. *For* \times N.P.D. $84^\circ.56'$ *read* \times N.P.D. $84^\circ.52'$. This star should precede B.A.C. 2118. Also in the same column Argelander 7143 should precede Bessel vi. 990.
- p. 45, third column. H. C. 14722 should follow Castor.
- p. 45, last column, 82 Geminorum. *For* -0.94 *read* -1.15 , and *for* 31.88 *read* 31.67. A mistake was made in calculating the correction.
- p. 47, last column. Bessel xiv. 439 is a mistake for Bessel xiv. 441, the correction should be -2.02 instead of -2.09 , and the seconds of R.A. 5.29 instead of 5.22. The date, correction, and R.A. should range under Bessel xiv. 441 above.
- p. 50, second column. *For* H. C. 32493 *read* H. C. 32486.
- p. 51, last column. *For* B.A.C. 6836 *read* B.A.C. 6386.
- p. 62, Feb. 10. *For* \circ Persei *read* 40 Persei, this being the name in all other instances.
- p. 62, Jan. 23. *For* Bessel iv. 1312 *read* Rumker 1382, the latter name being in accordance with the rule of nomenclature in p. i.
- p. 67, March 24, and p. 68, April 26. The star B.A.C. 3856 is 55 Ursæ Majoris, and should have been so called.
- p. 69, June 5. Add R to Zenith Point. The R is omitted also on Sept. 4 and 24, Oct. 15 and 29, Nov. 7, 19 and 20, and Dec. 31.
- p. 69, June 13. Circle observations were suspended from June 13 to July 10 in the absence of Mr Todd on vacation. This remark is omitted in the Notes.
- p. 72, Aug. 4. The microscope readings were $3'$ too great. The concluded Circle reading should be $70^\circ.0'.1''.35$; refraction, $170''.52$; and Apparent N.P.D. $109^\circ.7'.28''.59$.
- p. 73, column of concluded Circle readings. Dele the bar after the Zenith Points of Sept. 4.
- p. 82, Dec. 29. Dele the observation of Astræa, the object taken not being the Planet.
- p. 101, Nos. 222 and 223. Argelander 9164 and 9165 are the same star.
- p. 164, Jan. 23. The seconds of Apparent R.A. of λ Tauri should be 23.01, of Λ^1 Tauri 50.64, and of the Moon 46.01, being in each case $0''.05$ too small.
- pp. 169, 170 and 171, space below the columns. The Illumination was East, and the Intervals should consequently be $-40^s.344$, $-26^s.892$, $-13^s.573$, $-0^s.060$, $+13^s.618$, $+26^s.913$, $+40^s.337$.
- p. 213, Nos. 116 and 118, seconds of Mean R.A. *For* 22.68 *read* 22.73, and *for* 50.23 *read* 50.28.
- p. 217, No. 396. In the Note, *for* x. *read* xi.
- p. 228, Jan. 30. Dele M after \odot N.L. and \odot S.L., as being unnecessary.
- p. 228, line 11. *For* $D = -0''.026$ *read* $D = -0''.247$.
- p. 280, in the running Title. Dele the word APPARENT.
- p. 288, line 19. *For* $-0''.026$ *read* $-0''.247$, and *for* $+0''.105$ *read* $-0''.116$.
- p. 310, Feb. 18. The concluded transit and apparent R.A. of \odot 2 L are 1^m too small.
- p. 316, column of corrections of level error. The correction $+2''.0$ used on April 18, 19 and 21 is omitted.
- p. 325, column of corrections of azimuth error. *For* $+0.4$ *read* $+0.4$.
- p. 328, Aug. 21. Clock slow by β Aquarii, dele the brackets.
- p. 329, Sept. 3. Dele the observation of Hebe, the object observed not being the Planet.
- p. 337, Nov. 18. Seconds of concluded transit of Iris, *for* 53.72 *read* 52.74; seconds of meridian transit, *for* 53.77 *read* 52.79; and seconds of Apparent R.A. *for* 21.99 *read* 21.01.
- p. 339, Sept. 13. Seconds of Apparent N.P.D. of Iris, *for* 49.98 *read* 46.98.
- p. 384, Nov. 1. An observation of Ilygeia should be inserted after Neptune. See the Addenda to the Introduction, p. lxxvii.
- p. 410. The Geocentric N.P.D. and Parallax of Hebe on June 19, and the comparison of the R.A. and N.P.D. with the Tabular values, are omitted. See the Addenda to the Introduction, p. lxxvii.

CAMBRIDGE OBSERVATIONS.

INTRODUCTION.

THE *Instruments* and *Methods of observing* employed in taking the observations recorded in this Volume, are described in the Introductions to the Volumes of observations of 1838 and previous years. The following pages contain explanations of the tabulated observations and such occasional notices as could not be given at length in the body of the work, together with an account of the constants and formulæ used in the Calculations. Tables employed in the reduction of the observations are added to the Introduction.

OBSERVATIONS OF 1849.

1. *Apparent Right Ascensions observed with the Transit.* Pages 1—39.

The first division of the tabular portion of the work is allotted to the Transit Observations and the Calculation of Apparent Right Ascensions.

The *first column* contains the day of the month, supposed always to commence with the Sun's meridian passage.

The *second column* contains the names of the objects observed. With respect to nomenclature the following rules have been adhered to as closely as possible. Stars contained in the Nautical Almanac have the same names here given them as in that work. Stars in the Catalogue of the British Association, and not in the Nautical Almanac, are named in preference, by the letters in that Catalogue; next, by Flamsteed's numbers; and lastly, by the numbers of the Catalogue. The hour and number of Piazzi's Catalogue, the number of Groombridge's Catalogue, the number of Rumker's Catalogue of 12000 stars, and the number of Oeltzen's reduction of Argelander's zone observations from 45° to 80° of North Declination, have been used with the names of the respective observers attached, when the star is not in the Catalogue of the British Association. Double stars in Struve's *Catalogus Novus*, if not found in any of the above-mentioned works, and if they have been selected for micrometrical measurement with the Northumberland Telescope, are designated by the letter Σ prefixed to the number of that Catalogue. A star not coming under any of the above classes, if found in Weisse's reduced Catalogue of stars in Bessel's Zones (1846), is designated by the hour and number of that Catalogue preceded by the observer's name. If, not being in Weisse's Catalogue, the star is in the British Association reduced Catalogue of stars contained in the *Histoire Céleste* of Lalande, it is named by the number of this Catalogue with the letters H. C. prefixed. All other stars are designated by their approximate North Polar Distances.

In observations of double and multiple stars, the rule generally followed both in the Transit and Circle observations is, to select the brightest when decidedly brighter than the others, and of two or more nearly equally bright, to take the preceding. Sometimes the observer notes the one selected as *preceding, following, north, south, north preceding, north following, south preceding, south following*, by the letters *p, f, n, s, np, nf, sp, sf*, in their usual signification, the preceding star being that of less R.A., and the north star that of less N.P.D. This is done when the application of the foregoing rule is doubtful, or when the stars are very close, to shew that they are seen separate, or to facilitate the identi-

fying of the stars. The above letters are placed after the names of the stars in the second column, only in case the observer has thus noted at the time of observation the star selected.

The *seven succeeding columns* contain the seconds, by the Transit clock, of the times of passage over the seven wires. It has been thought unnecessary to give the hours and minutes, as they may be readily inferred, by means of the Table of intervals below, from the concluded time of transit over the mean of the seven wires, given in the next column.

When, as not unfrequently happens from atmospheric and accidental causes, the times of transit across all the wires cannot be observed, a correction is necessary for reducing the mean of the observed times to the time of transit over the mean of all the wires. This reduction is effected by adding (with the proper sign) to the mean of the observed times, the sum of the distances in time of the omitted wires from the mean of all, divided by the number of the observed times. (See Introduction to the Observations of 1836, p. xiii.)

The following table of intervals of the seven wires from the mean of all, which was used throughout the year, was computed from nine complete transits of δ Ursæ Minoris and twenty complete transits of Polaris taken from 1847 January 14 to 1848 April 4. It was ascertained by six complete transits of Polaris in 1849 that the intervals during that year remained very nearly the same as in 1848. The wires are distinguished by the letters *A, B, C, D, E, F, G*; and stars above the Pole pass them in this order when the Illumination end of the axis is East.

Wire.	Interval for an Equatorial Star.	Interval for Polaris. Declination = $88^{\circ}.29' + n''$.	Interval for δ Ursæ Minoris. Declination = $86^{\circ}.35' + n''$.
A	$-40,362$	$-25.28,11 - 0,281 n$	$-11.17,54 - 0,055 n$
B	$-26,890$	$-16.56,90 - 0,187 n$	$-7.31,29 - 0,037 n$
C	$-13,537$	$-8.31,58 - 0,094 n$	$-3.47,14 - 0,018 n$
D	$-0,065$	$-2,47$	$-1,10$
E	$+13,616$	$+8.34,56 + 0,094 n$	$+3.48,48 + 0,019 n$
F	$+26,877$	$+16.56,40 + 0,187 n$	$+7.31,07 + 0,037 n$
G	$+40,362$	$+25.28,09 + 0,281 n$	$+11.17,52 + 0,055 n$

The intervals for all other stars were obtained by multiplying the intervals for an equatorial star by the cosecant of N.P.D., and those for the planets by multiplying by the additional factor $1 + \frac{I}{3600}$, I being the horary variation of the planet's R.A.

The position of the Transit is indicated in the space immediately below the columns by the terms 'Illumination East,' or 'Illumination West,' according as the pivot which is perforated to admit the light of a lamp for illuminating the field of view, is East or West. In the same space the above Equatorial Intervals are inserted in the order in which they are passed over by a star above the pole.

The concluded times of transit over the mean of the seven wires, as given by the clock, are placed in the *tenth column*. When the object has been observed at all the wires, the concluded time is merely the mean of the times at the seven wires. In case of an incomplete observation, the concluded time is the mean of the noted times corrected for the omitted times in the manner already explained.

The columns which next follow contain steps of the calculation by which the Apparent Right Ascensions are inferred from the concluded times of transit; which is done by applying corrections for *Collimation Error*, *Level Error*, *Azimuth Error*, and *Clock Error*. The methods of obtaining these corrections will here be severally stated in the order of their application.

Collimation Error.—The errors of collimation in 1849 were determined exclusively by the collimating eye-piece. The following is the method of using this instrument.

A moveable wooden stage in the Transit Room, (intended originally for taking transits by reflexion for the determination of Level Error), is made to pass over the West Pier by running on a kind of rail-way, and gives the observer a position in which he can look through the Telescope when directed to the Nadir. The form of the collimating eye-piece which I use, is a common inverting microscope of three lenses, to which is attached, beyond the third lens, a piece of plate-glass, inclined at an angle of 45° to the axis of the microscope. The eye-piece of the Telescope being removed, this apparatus is put in its place, so that the plate-glass is between the wires and the microscope; and when the Telescope is directed vertically to a trough of mercury, the wires and their images by reflection become visible as dark lines on a bright ground, by throwing the light of a lamp on the plate-glass. That the wires and their images may be distinctly seen at the same time, it is necessary that the wires should be accurately in the geometrical focus of the object-glass of the Telescope. The position of the wires of the Transit Telescope was found to satisfy this condition very nearly and has consequently not been changed.

The determination of the collimation error of the middle wire is effected by measuring with the micrometer-wire the interval between the middle wire and the position of the micrometer-wire when it exactly coincides with its own image. This interval, expressed in arc, is the sum or difference of the level error and the collimation error of the middle wire. Hence the level error being ascertained at the time by the Spirit Level, the collimation error becomes known.

This method supposes the pivots to be exactly cylindrical. As the pivots of the Cambridge Transit do not satisfy this condition, I have not trusted to the collimating eye-piece for absolute determinations of error of collimation. Several contemporaneous determinations having been made by the two methods, by comparison of the results two constants have been obtained for correcting the values given by the collimating eye-piece, one for Illumination East and the other for Illumination West. Thus virtually the collimation error is determined by the usual method, and the collimating eye-piece is merely employed as an auxiliary, the use of which is very convenient on account of its being independent of the condition of the atmosphere.

Let l_w = the true level error, (that is, the angular elevation of the West end of the axis), the Telescope being directed to the Nadir and the Illumination *West*.

c = the collimation error of D , (that is, the deviation of D from the true line of collimation Westward) Illumination *West*.

a = the deviation of D Eastward from the vertical plane through the optical centre of the object-glass, as measured by the collimating eye-piece, Illumination *West*.

L_w = the level error as determined immediately by the Spirit Level, the Telescope being horizontal and directed Southward, and Illumination *West*.

and let l_e , $-c$, b , and L_e be respectively the same quantities when the Illumination is East. Then, since the deviation of D from the vertical plane towards the East is equal to the level error diminished by the collimation error, we have

Collimation Error of D (Illumination West) = $c = l_w - a$,

Collimation Error of D (Illumination East) = $-c = l_e - b$.

The constant values of $l_w - L_w$ and $l_e - L_e$ adopted in 1849 are $+0''.84$ and $+0''.73$, which were deduced from those used in 1848, as stated further on in the account of the reversion of the Transit on Aug. 24. Since by the Table in page ii, the mean of all the wires is nearer to the Illumination end of the axis than D by $0''.98$, the following are the formulæ for the error of collimation of the mean of the wires, inclusive of the correction $-0''.18$ for diurnal aberration:

Error of Collimation of the mean of the wires (Illumination West) = $L_w - a + 1''.64$,

Error of Collimation of the mean of the wires (Illumination East) = $L_e - b - 0''.43$.

These formulæ are used throughout the year. The following are the particulars of the several determinations of collimation error in 1849 by the collimating eye-piece.

Feb. 28, 4^h. Determination of the collimation error by the collimating eye-piece. The reflected images oscillated. The temperature of the Transit Room was $42^{\circ}.6$.

Illumination East.

Mean of 6 readings, micrometer-wire coinciding with its image.....	r . 23,516
..... 6 with D	23,841

Hence the micrometer reading for coincidence with the vertical plane through the optical centre of the object-glass was less than that for coincidence with D ; and since the readings increase as the micrometer-wire is moved towards the micrometer-head, that is, *from* the Illumination end of the axis, it follows that D was to the *West* of the vertical plane by $0''.325$. Hence $b = -5''.54$, the values of r being $17''.06$. And by the Table of Level Errors in p. vii, $L_e = -4''.12$. Consequently $L_e - b - 0''.43 = +0''.99$. Hence the collimation error to the nearest tenth of a second is $+1''.0$, which is used from the beginning of the year.

Feb. 28, 5^h. Determination of the collimation error as above, after reversing the Transit. Great oscillation of the image of the micrometer-wire.

Illumination West.

Mean of 6 readings, micrometer-wire coinciding with its image.....	r . 24,073
..... 6 with D	23,835

Hence D was to the *West* of the vertical plane by $0''.238$, and consequently $a = -4''.06$. Also by the Spirit Level $L_w = -6''.06$. Hence $L_w - a + 1''.64 = -0''.36$, which is the collimation error of the mean of the wires. The value adopted from the time of the reversion on Feb. 28 is $-0''.4$.

July 2, 9^h. The error of collimation was determined by Mr Breen with the collimating eye-piece. The mercury was agitated by wind.

Illumination West.

Mean of 10 readings, micrometer-wire coinciding with its image	r . 23,771
..... 7 with D	23,903

Hence D was to the *East* of the vertical plane by $0''.132$, and $a = +2''.25$. At the same time $L_w = +0''.73$. Hence $L_w - a + 1''.64 = +0''.12$. The value $+0''.1$ is used from May 2.

Aug. 24, 3^h. Error of Collimation by the collimating eye-piece. The micrometer reading for the coincidence of the micrometer-wire with its image is inferred from seven readings taken by placing the micrometer-wire midway between D and its image, and four readings for coincidence of the micrometer-wire alternately with D and with its image.

Illumination West.

Mean of 11 readings, micrometer-wire coinciding with its image	r. 23,699
..... 8 with <i>D</i>	23,892

Hence *D* was to the East of the vertical plane by $0''.193$, and $a = +3''.29$. And as by levelling $L_w = +0''.78$, it follows that $L_w - a + 1''.64 = -0''.87$.

Aug. 24, 5^h. The Transit was reversed under circumstances not altogether favourable. The cross waved very much before the reversion, but was steady and distinct after the reversion. The image of the collimator's wire is too indefinite for satisfactory bisection. The definition was improved by putting a large piece of paper on the tube of the collimator, so as to prevent light falling horizontally on the object-glass of the Transit Telescope.

Illumination West.

Mean of 6 readings, micrometer-wire coinciding with <i>D</i>	r. 23,908
..... 6 bisecting South mark	24,345
..... 8 bisecting North mark	25,361

Illumination East.

Mean of 7 readings, micrometer-wire bisecting North mark	r. 22,292
..... 6 bisecting South mark	23,384
..... 6 coinciding with <i>D</i>	23,900
Reading for line of collimation by South mark	23,864
..... North mark	23,827
Reading for true line of collimation	23,845
Reading for coincidence with <i>D</i>	23,904

Since the readings increase as the micrometer-wire moves from the Illumination, after the reversion stars entering from the West came to *D* before coming to the true line of collimation. Hence the error of collimation of *D* was ± 0.059 according as the Illumination was East or West, or in arc, $\pm 1''.01$. This result is only used for correcting the values of the constants $l_w - L_w$ and $l_e - L_e$.

Aug. 24, 6^h. After the reversion of the Transit the collimation error was determined by the collimating eye-piece. The reading for coincidence of the micrometer-wire with its image was inferred from five readings taken when the micrometer-wire, the wire *D*, its image, and the image of the micrometer-wire were placed at equidistant intervals, and from five readings taken after reversing the positions of the micrometer-wire and its image.

Illumination East.

Mean of 10 readings, micrometer-wire coinciding with its image	r. 24,032
..... 6 with <i>D</i>	23,892

Hence *D* was to the East of the vertical plane by $0''.140$, and $b = +2''.39$. And by the Spirit Level $L_e = +2''.98$. Hence $L_e - b - 0''.43 = +0''.16$. The value $+0''.2$ is used on Aug. 24, the Illumination being East during the observations of that day.

By the formulæ in p. iv, $l_w = a + c$ and $l_e = b - c$, *c* being the collimation error of *D*, Illumination West, as determined by reversing the instrument. Hence by the measures taken on Aug. 24, $l_w = +3''.29 - 1''.01 = +2''.28$; and $l_w - L_w = +2''.28 - 0''.78 = +1''.50$. Also $l_e = +2''.39 + 1''.01 = +3''.40$; and $l_e - L_e = +3''.40 - 2''.98 = +0''.42$.

The values of $l_w - L_w$ and $l_e - L_e$ used in 1848, viz. $+0''.76$ and $+0''.77$, depended on eight determinations. By giving, therefore, to the above results a weight of one-ninth, we obtain $l_w - L_w = +0''.84$ and $l_e - L_e = +0''.73$, which are the values adopted for 1849.

Aug. 26, 22^h. Determination of the collimation error by the collimating eye-piece. The Transit had been reversed on Aug. 25 at 3^h. The micrometer-wire was placed midway between *D* and its image.

Illumination West.

Mean of 7 readings, micrometer-wire coinciding with its image.....	^{r.} 23,729
..... 7 with <i>D</i>	23,866

Hence *D* was to the East of the vertical plane by 0',137, and $a = +2'',34$. By levelling Aug. 26, 22^h, $L_w = +0'',78$. Therefore $L_w - a + 1'',64 = +0'',08$. The mean between this determination and that on Aug. 24, viz. $-0'',87$, is $-0'',40$. This value is adopted from Aug. 3.

Nov. 22, 0^h. Error of Collimation by the collimating eye-piece. Nine readings for coincidence of the micrometer-wire with its image were taken, but the first three, which exceeded the remainder by about 0',02, were rejected. A like discordance has been noticed on other occasions. In the course of these measures, the same micrometer reading was obtained when the micrometer-wire was moved in opposite directions to make the bisections.

Illumination West.

Mean of 6 readings, micrometer-wire coinciding with its image.....	^{r.} 23,680
..... 6 with <i>D</i>	23,882

Hence, as above, $a = +0',202 = +3'',45$. And as $L_w = +1'',40$, it follows that $L_w - a + 1'',64 = -0'',41$. In consequence of this result the value $-0'',4$ has been used to the end of the year.

The values of collimation error, adopted in the reduction of the transits, are placed in the *eleventh column*, with bars across to indicate the interval during which each value is used.

The correction to the observed time of each transit is in seconds of time,

$$\frac{1}{15} \times \text{collimation error} \times \text{cosecant of N.P.D.},$$

the N.P.D. being considered negative when the star passes below the pole.

Level Error.—The angular deviation of the axis of revolution of the Transit from a horizontal plane is found by applying to the pivots a Spirit Level, furnished with a cross-level adjustment, and with graduated scales for reading off the positions of the extremities of the bubble. It is the practice to reverse the level five times, and thus obtain six eastern and six western readings, the scales being first disposed in positions convenient for reading off, which they retain during the whole of the operation. In the graduation of each scale the numbers increase in the direction from the middle of the bubble towards the extremity. Hence the algebraic excess of the sum of the western above the sum of the eastern readings, divided by the whole number of readings, is the measure, in scale-intervals, of the elevation of the west end of the axis above a horizontal plane. This is converted into angular measure by multiplying by 1'',3, the value of the scale-interval. Since stars above the pole require a positive correction to their time of transit when the west end of the axis is the more elevated, the result thus obtained is the level error with the sign proper for the application of that correction.

The levelling is generally performed once in a week, and the determination is used from the third or fourth day previous. The values of level error adopted in the reduction of the transits are placed in the *twelfth column*, with bars across to indicate the interval during which each value is used.

The following Table contains a list of all the Level Errors obtained in 1849, with the times of levelling, position of the instrument, and Temperature in degrees of Fahrenheit, as shewn by a Thermometer in the Transit Room. In all the levellings, with the exception mentioned below, the Telescope was horizontal, and the object-glass southward.

Level Errors in 1849.

* * In the reduction of the observations the above values of level error are taken to the nearest tenth of a second.

After the first levelling of Feb. 28 I cleaned the pivots, which had become very foul, the instrument being raised from the Y's for this purpose. The next levelling seems to shew that the level error was not affected by this state of the pivots.

April 21, 5^h, I turned the screws of the east pier to diminish the level error. The reading of each screw-head was increased by 2,1 intervals.

The first levelling on Aug. 26 was taken in the usual manner, the feet of the level being applied to parts of the pivots which appear to be a little worn by the continual application of the level. In the other levelling the telescope was pointed 45° south of the zenith, and the feet of the level were applied to parts of the pivots not worn in the same manner. The result of the latter levelling is not made use of.

The levellings from Sept. 12 to Oct. 11 inclusive, with the exception of the first of Sept. 18, were taken by Mr Carrington. The second levelling of Oct. 8 was taken after lighting the lamp for illuminating the field of view of the telescope, and leaving it in its usual position at the end of the pivot for ten minutes. The levelling of Oct. 11 was taken after the illuminating lamp had been in its place all the previous part of the night. The scales were read off with difficulty by a lamp held near the observer's head, which seemed to have the effect of causing variations of the bubble. The effect of the heat of the illuminating lamp on the level error seems to be inappreciable. The mean result of the two levellings on Sept. 18 is used from Sept. 17: the second levelling of Oct. 8, in which the level was applied only four times, is not taken into account.

The correction for the unequal radii of the pivots, obtained in the manner explained in Vol. X. p. xxviii, is -0",45 by the second and third levellings of Feb. 28, and -0",51 by the levellings of Aug. 24. These results, compared with those in p. li of Vol. XVII, indicate the progressive effect of applying the feet of the level to the same parts of the pivots, rather than a change in the radii of the pivots. See the remark above on the levellings of Aug. 26.

The correction applied to the observed time of each transit, previously corrected for error of collimation, is

$$\frac{1}{15} \times \text{lever error} \times \cosine \text{ of Zen. Dist. } \times \text{cosec. of N.P.D.,}$$

the N.P.D. being negative when the star is below the pole.

In addition to the corrections for level error by the above formula, corrections have been applied (previous to the determination of azimuth error) for variations of level error due to the forms of the pivots, according to the subjoined Table, the formation of which is explained in pages xlix—lii of the Introduction to Volume XVII.

N.P.D.	Correction Illum. W.	Correction Illum. E.	N.P.D.	Correction Illum. W.	Correction Illum. E.
-37° to -17°	-0,01	+0,01	32° to 77°	-0,01	+0,01
δ Ursæ Min. SP.	+0,25	-0,15	77 ... 78	-0,01	+0,02
Polaris SP.	+0,53	-0,39	78 ... 87	-0,01	+0,01
Polaris	-0,49	+0,47	87 ... 90	0,00	+0,01
δ Ursæ Minoris	-0,20	+0,20	90 ... 107	0,00	0,00
+20° to 24°	-0,03	+0,03	107 ... 112	+0,01	0,00
24 to 32	-0,02	+0,02	112 ... 128	0,00	0,00

Azimuth Error.—The angle by which the plane of motion of the true line of collimation (supposing the level error corrected), deviates from the plane of the meridian, has been generally found by two or more transits of Polaris, or δ Ursæ Minoris, alternately above and below the pole, and as often as possible, consecutive. When this method could not be employed, the azimuth error has been deduced from a comparison of a single transit of one of these stars with the transit of a known star above and distant from the pole.

The formulæ of calculation applicable to these methods are obtained as follows. Let A, A' be the apparent right ascensions of two known stars, t, t' their times of transit as shewn by the clock, corrected for collimation and level errors, τ the clock's loss in the interval between the transits, h, h' , the coefficients of azimuth error, calculated by the formula, coefficient = $\frac{1}{15} \sin. \text{Zen. Dist.} \times \text{cosec. N.P.D.}$, and therefore positive except between the zenith and the pole, and z the azimuth error in seconds of space, considered positive when it causes the plane of motion of the line of collimation to deviate on the South side of the Zenith towards the East. Then

$$A' - A = t' + h'z + \tau - (t + hz),$$

$$\text{or } z = \frac{A' - A - (t' - t) - \tau}{h' - h},$$

which is the general formula for azimuth error. That it may be safely used, the denominator $h' - h$ must be large, and it is consequently necessary that one at least of the stars should be near the pole.

When two known stars, one or both near the pole, are employed, $A' - A$ is the difference of their assumed apparent R.A., and τ is inferred from the differences of the uncorrected times of transit of any southern star observed on two days near the time of the observations made use of for azimuth error.

If two observations of the same polar star be used, one above and the other below the pole, and if ϵ be the increase of its R.A. in the interval between the observations, $A' - A = 12^h + \epsilon$, and

$$z = \frac{12^h + \epsilon - (t' - t) - \tau}{h' - h},$$

which is independent of any assumed R.A. of the star.

When three equidistant transits of a polar star, alternately above and below the pole, have been obtained, there will be another equation like the preceding, in which ϵ and τ have nearly the same values; and if t'' be the time of the third transit, corrected for errors of collimation and level, the two equations give

$$z = \frac{(t'' - t') - (t' - t)}{2(h' - h)},$$

which equation is independent both of the R.A. of the stars, and of their change of R.A. and the clock's rate.

The numerical computation from the preceding formulæ is performed as follows, the azimuth error being always a small quantity. The seconds of transit of the stars being first corrected for collimation and level errors, when two stars are used, the seconds of transit of the second are further corrected for the loss of the clock in the interval between the transits. From the seconds thus corrected the seconds of the sidereal interval between the transits, affected only by azimuthal error, are deduced. The seconds of the same interval are then inferred from the seconds of the assumed R.A. of the stars. The algebraic excess of the latter difference above the former (care being taken to add or subtract 60^s that the excess may not contain a large number of seconds) is the azimuthal correction of the interval between the transits. This quantity divided by $h'-h$, the algebraic excess of the coefficient of azimuth error for the second star above that for the first, gives the azimuth error with its proper sign. The process is the same in the case of two transits of a polar star, one above and the other below the pole, the change of the star's R.A. in the interval being taken into account.

When there are three consecutive transits of a polar star, the change of the star's R.A. and the clock's rate are not considered, and the adopted azimuth error is the mean of the two results which would be obtained by the above rule from the first and second, and from the second and third. If more than three consecutive transits be observed, a value of the azimuth error is deduced from the first, second, and third; another from the second, third, and fourth; and so on. If the different values are nearly equal, the mean of all would be used; otherwise they would be used separately or in groups.

The following Table contains a list of the Azimuth Errors in 1849, with the data employed in calculating them, by means of which they may be readily verified.

Calculation of Azimuth Errors in 1849.

Approximate Mean Time of observation.	Star.	Seconds of transit corrected for Collimation and Level Errors.	Correction for rate of Clock.	Seconds of the Star's assumed R.A.	Azimuthal Correction of the Interval between the transits.	Value of $h'-h$.	Azimuth Error.	Remarks.
Jan. 26. 9 26. 10	α Orionis δ Ursæ Min. SP.	3,91 46,12	+ 0,02	0,90 44,04	+ 0,91	+ 0,693	+ 1,31	Used from Jan. 14. The azimuth error used from the beginning of the year to the end of Jan. 6 is +1",8, as determined 1849 Dec. 21.
Jan. 30. 13 30. 21 31. 5	Regulus δ Ursæ Minoris α Arietis	23,07 47,66 42,77		20,68 44,98 40,34	- 0,29 + 0,25	- 0,679 + 0,671	+ 0,43 + 0,37	The mean of these is used from Jan. 29. The intervals between the observations being nearly equal, the clock's rate is not taken into account.
Feb. 8. 8 8. 9	α Orionis δ Ursæ Min. SP.	58,43 43,07	+ 0,01	0,78 46,67	+ 1,25	+ 0,693	+ 1,82

*. * In the reduction of the observations the above values of the azimuth error are taken to the nearest tenth of a second.

The assumed apparent R.A. employed in the above calculations are the R.A. of the Nautical Almanac, corrected by the small quantities mentioned under the head of Clock Error in page xiii.

The azimuth errors adopted in the reduction of the transits are placed in the *thirteenth column*, with bars across to indicate the interval during which each value is used. The correction in seconds of time applied to each Transit is,

$$\frac{1}{15} \times \text{azimuth error} \times \sin. \text{ of Zen. Dist. } \times \text{cosec. N.P.D.,}$$

the zenith distance being negative to the north of the zenith, and the north polar distance negative to the north of the pole.

The seconds of transit of each object, corrected for the errors of collimation, level, and azimuth, are arranged in the *fourteenth column*. If the three errors be called respectively a , b , c , and if δ be the north polar distance of the object, and z the zenith distance south, that is, the algebraic excess of δ above $37^{\circ}.47'.8''$, the co-latitude of the Observatory, then the sum of the three corrections is,

$$a \cdot \frac{1}{15 \sin \delta} + b \cdot \frac{\cos z}{15 \sin \delta} + c \cdot \frac{\sin z}{15 \sin \delta}.$$

The computation of this quantity has been generally performed by means of a machine constructed by Mr Simms under my direction, a description of which is given in the Monthly Notices of the Royal Astronomical Society, Vol. X. p. 182. The machine calculates at once the above quantity when a , b , c , and δ are given, and saves the trouble of writing down the coefficients of a , b , and c . The result it gives is accurate to the hundredth of a second, if the star be not very near the pole. It has not been used in the reductions of the observations of Polaris and δ Ursæ Minoris, nor in the calculation of azimuth error. In these instances Table II. at the end of this Introduction has been employed. Table I., though not used, is added to facilitate the verification of the calculations.

Clock Error.—The errors of the Clock are the excesses of the assumed apparent right ascensions of the stars which have been selected for the determination of true sidereal time, above the clock times of meridian transit. The assumed Mean Right Ascensions, Jan. 1, 1849, of these fundamental stars are given in the subjoined Table, in which Polaris and δ Ursæ Minoris are included, because their apparent right ascensions are employed for finding the azimuth error.

The assumed Mean Right Ascensions were obtained by adding the annual variations to the Mean Right Ascensions, Jan. 1, 1848, concluded from the observations of 1848, whenever the number of observations from which the R.A. of any star was concluded, was not less than twenty. In other cases, if A be the assumed R.A. of 1848, and if A' be the R.A. resulting from a number (n) of observations in that year less than 20, the assumed R.A. of 1849 is $A + (A' - A) \frac{n}{20}$ increased by the annual variation. The mean excess of the assumed R.A. of the fundamental stars above the R.A. of the Nautical Almanac is + 0^s.089, which agrees very nearly with the result of the observations of 1848.

To form the assumed apparent R.A. used for the determination of the azimuth error and the error of the clock, the excesses above the Nautical Almanac in the foregoing table, are added to the apparent R.A. of that work. It will be seen that the corrections which are thus adopted for aberration, precession, and nutation, are the same as those of the Nautical Almanac, which assume the constant of aberration to be $20''.36$, and that of lunar nutation to be $9''.25$. The assumed apparent R.A. of Polaris and δ Ursæ Minoris take account of the additional corrections, depending on the Moon's longitude, which are given in pages 502 and 503 of the Nautical Almanac for 1849. In all cases in which the stars are used for the determination of azimuth error, the seconds of the assumed R.A. are inserted in the Table of azimuth errors already given in this Introduction.

The clock errors in the *fifteenth column* are the excesses of the assumed apparent right ascensions of the fundamental stars above the times of meridian transit. The times of putting forward the minute-hand of the clock are stated in the space immediately below the columns. This notice is inadvertently omitted between Aug. 24 and Aug. 28. The clock accidentally stopped three times in the course of the year, as mentioned in the notes, and during cold weather the rate was accelerated and was somewhat irregular. After being cleaned at the end of the year its rate was more steady.

For the purpose of calculating the correction to be applied to each observation for error of the clock, the observations are divided into groups severally containing stars proper for giving clock errors. These groups, the limits of which are marked by bars across the column of clock errors, are separated by intervals during which no observations have been taken, and which, as often as possible, belong to consecutive nights. The mean of the clock errors in each group is considered to apply to the mean of the times of transit of the stars which furnish them. The comparison of this mean error with errors similarly derived from the next preceding and following groups, gives a preceding and a following rate; whence a rate is inferred, which is assumed to hold uniformly throughout the middle group. No definite rule can be given for inferring the adopted rate: attention is paid to the probable relative accuracy of the rates on which it depends, and also to the proportion of the intervals separating the preceding and following mean clock errors from the intermediate one. Those clock errors which are included in brackets are not used for determining the clock's rate.

When in the same group there are clock errors by two observers, the clock's mean error and rate are entirely derived from the observations of one observer, and the clock errors of the other are put in brackets, being only used for finding the difference of their personal equations. The apparent R.A. from the observations of the latter observer are corrected for this difference. This rule has been applied to observations of Mr Carrington (C) and Mr Breen (B) from Sept. 22 to Oct. 12. In several instances the same star was observed by both observers at the same transit, the times being taken at four wires by one and at three by the other, for the express purpose of determining difference of personal equation. In these cases, the two sets of transits are reduced as if they belonged to different objects, but the mean of the two results is considered to be the apparent R.A. from observation. The following is the calculation of the difference of personal equations of C and B, the mean clock errors of the two observers on the same day being first reduced to the same epoch.

Day of Observation, 1849.	Clock's loss by B.	No. of B's Obser- vations.	Clock's loss by C.	No. of C's Obser- vations.	Excess of B's Clock error.	Assumed Weight.
Sept. 22	20,70	1	20,32	2	+ 0,38	1
24	21,95	3	21,82	3	+ 0,13	5
25	22,90	6	22,54	2	+ 0,36	6
26	23,76	4	23,86	2	+ 0,40	4

Taking account of the assumed weights of the several results, the mean excess of B's clock error is $+0''.30$, that is, B observes *earlier* than C by this interval. Hence as the clock's adopted error and rate are deduced from B's observations, those of C on Sept. 24, 25, 26, and Oct. 2, are corrected by $-0''.30$.

Another determination of the difference of the personal equations of B and C was similarly derived from observations from Oct. 8 to Oct. 12, as follows:

Day of Observation, 1849.	Clock's loss by B.	No. of B's Obser- vations.	Clock's loss by C.	No. of C's Obser- vations.	Excess of B's Clock error.	Assumed Weight.
Oct. 8	27,52	5	27,32	2	+ 0,20	5
9	27,46	4	27,10	2	+ 0,36	4
10	27,34	7	27,05	2	+ 0,29	7
11	27,15	3	26,63	1	+ 0,52	1
12	27,26	3	26,82	2	+ 0,44	3

In addition to the observations of fundamental stars from which the foregoing results were derived, there were observations of other stars taken partly by one and partly by the other observer at the same transits, which when reduced to the mean of all the wires gave the following differences:

Day.	No. of Ob- servations.	Mean Excess of C's time.	Assumed Weight.
Oct. 9	2	+ 0,48	2
10	1	+ 0,08	1
12	2	+ 0,40	2

The eight different results taken with their respective weights give as a mean result $+0^s.33$. Hence C's apparent R.A. from Oct. 8 to Oct. 12 have been corrected by $-0^s.33$. It may be remarked that the last difference of personal equation is the same as that between myself and Mr Breen, as determined in Vol. XVII. p. xxxv, and very nearly the same as that between Mr Todd and Mr Breen, as determined in page lv of the same volume, so that three of the four observers appear to observe alike.

The single observation of Mr Breen on Dec. 19 is only used for finding a value of the difference between his personal equation and that of Mr Todd. Differences of personal equation are taken into account when necessary, in deducing the clock's rate from groups of observations taken by different observers.

The adopted rate, determined in the manner above stated, is placed in the *sixteenth column*, with bars across to mark the limits within which it is used. These limits generally coincide with the limits of the groups of observations.

The Apparent Right Ascensions from observation, given in the *seventeenth column*, are deduced as follows from the clock times of meridian transit. The adopted rate is employed, first, in calculating from the mean clock error of the group to which it applies, the correction for clock error at each 0^h of sidereal time which occurs within the limits of the group, and then in finding the additional correction for the interval between each transit and the next preceding 0^h . The result of adding the sum of these corrections to the time of meridian transit is the apparent R.A. concluded from the observation. The apparent R.A. of the fundamental stars, if fewer than three are contained in the same group, and the apparent R.A. of Polaris and δ Ursæ Minoris, if the azimuth error is not determined by two or more transits of one of these stars, are not inserted in the column of apparent R.A.

The *eighteenth column* contains the initial of the observer's name, the letters C, B, and T indicating respectively observations taken by Mr Carrington, Mr Breen, and Mr Todd.

The notes in the space at the bottom of the page consist of incidental and explanatory remarks, and such as may serve to identify the stars. To give an opportunity of judging of the weight due to individual observations, it was thought right to omit the mention of no circumstance which seemed likely in any way to affect the result of an observation.

II. *Mean Right Ascensions of the Stars as deduced from the separate observations, with the Corrections applied to the apparent Right Ascensions.*

The columns in pages 42—60 contain the names of the stars arranged in order of right ascension, the days on which each star was observed, the corrections (for aberration, precession, and nutation) which have been added algebraically to the apparent Right Ascensions extracted from the columns of 'Apparent R.A. from observation,' in pages 1—39, and the resulting mean Right Ascensions, Jan. 1, 1849. The corrections are calculated as follows.

For stars whose apparent Right Ascensions are given in the Nautical Almanac, the corrections are obtained by subtracting the apparent from the mean Right Ascensions of that work, after applying to the former in the instances of Polaris, and δ Ursæ Minoris, the small corrections in pages 502 and 503. For a star in the Catalogue of the British Association, and not included in the list of the Nautical Almanac, the correction (δa) is calculated by the formula,

$$-\delta a = Aa + Bb + Cc + Dd,$$

$\log A$, $\log B$, $\log C$, and $\log D$ being taken without alteration from the Nautical Almanac, and $\log a$, $\log b$, $\log c$, $\log d$, from that Catalogue. The formula employed for all other stars is, as in preceding years,

$$\begin{aligned} -\delta a = & \frac{A}{15} \cos \text{R.A.} \operatorname{cosec} \text{N.P.D.} + \frac{B}{15} \sin \text{R.A.} \operatorname{cosec} \text{N.P.D.} + C \times [0,4869] \\ & + \frac{C}{15} \times [1,3020] \times \sin \text{R.A.} \cotan \text{N.P.D.} + \frac{D}{15} \cos \text{R.A.} \cotan \text{N.P.D.}, \end{aligned}$$

the numerical constants printed in the skeleton forms for calculation being suffered to remain unaltered. The more correct values are 0,4872 and 1,3022.

III. *Apparent North Polar Distances observed with the Mural Circle.*

The particulars of observations with the Mural Circle, and the data for calculating the apparent North Polar Distances, are contained in pages 62—82. The following is the explanation of the contents of the separate columns.

The *first column* has the day of observation, commencing always with the Sun's passage.

The *second column* contains the name of the object observed. The letter *R* following the name, denotes that the object was observed by reflexion in a trough of mercury. The stars are named according to the rule adopted with respect to the Transit observations. Anonymous stars are designated by their approximate mean right ascensions.

The order of the six microscopes, beginning with *A*, which is at the northern extremity of the horizontal diameter of the circle, and proceeding over the highest part of the limb, is *ACEBDF*, so that *A* and *B*, *C* and *D*, *E* and *F*, are severally at the ends of a diameter. The order of the graduation is from South to North through the highest point of the circle. All micrometer readings increase as the micrometer wires move *towards* the graduated micrometer-heads. The microscopes have their micrometer-heads all directed the same way relatively to the graduation of the circle: that of *A* is *downwards*. When the Telescope is horizontal and its object-glass looks southward, the micrometer-head of the eye-piece micrometer is also downwards.

The *six succeeding columns* contain the readings of the six microscopes. The divisions of the graduation of the circle are 5' apart. The minutes, which are set down in the first of these columns, are indicated by the number of indents of the comb of the microscope in the interval between the division bisected by the micrometer wire and the hole of the comb; and the seconds and fraction of a second are taken from the micrometer-heads. The bisected division is that next to the hole, on the *same* side, as seen in an inverting microscope, as the micrometer-head, excepting in some instances mentioned hereafter.

The microscope readings taken in the manner just stated, are affected with an error of *Runs*, unless the micrometer wire is carried by five turns of the micrometer exactly from the image of one division to that of the next, which very rarely happens to be the case. The corrections applied on this account, are obtained in the following manner. The Circle being clamped in such a position that a division is near the zero of the

The correction for Runs was ascertained at each determination of the zenith point, the Telescope being directed to the Nadir, and the value so found is employed in calculating the zenith point. The Runs were also frequently taken about the same time after placing the Telescope in an arbitrary position. In all cases in which the Runs were taken twice on the same day, the mean between the two results is used in the reduction of the observations, excepting that $+5''.3$ was inadvertently used on Jan. 15—30 instead of $+5''.5$. The Runs adopted on Jan. 2 and 5, were obtained on Dec. 20, 1848. The first determination of April 3, made by myself after the measures for finding the value of one revolution of the Telescope micrometer, is only employed in calculating that value; and the second of May 14 was not required for reducing the observations. In general the adopted correction is used about as long before as after the date of its determination.

The readings of the micrometer for bisections of the objects named in the second column are put in the *tenth column*, unless the reading be $10'.000$, which answers to the reference position of the micrometer-wire.

The amount of correction for reducing an observation to the reference position of the micrometer-wire, is the difference between the recorded micrometer-reading and $10'.000$, converted into arc by multiplying by $20''.862$, which is the arc corresponding to one revolution of the micrometer-head. The correction is positive or negative, according as the micrometer-reading is less or greater than $10'.000$.

April 3, 5^h—6^h, I observed as follows for determining the value of one revolution of the Telescope micrometer. The mark was beautifully steady and distinct, and the bisections were satisfactory, but the atmospheric refraction was apparently changing. The Temperature by the In-door Thermometer on the Pier was $47^{\circ}.3$, and by the Out-door Thermometer $46^{\circ}.7$.

Micrometer reading.	Pointer reading.	Microscope A	B	C	D	E	F	Correction for Runs.	Concluded Circle reading.	Difference.	Mean of consecutive differences.
- 15	88. 30	1. 45,3	44,5	44,2	52,8	45,6	46,1	+ 1,9	88. 31. 46,73	" "	" "
+ 15	88. 40	2. 9,5	7,7	9,8	16,5	8,5	9,6	+ 2,3	88. 42. 10,65	10. 23,92	10. 25,85
- 15	88. 30	1. 43,3	42,0	41,4	49,6	41,9	43,2	+ 1,9	88. 31. 43,88	10. 26,77	10. 25,92
+ 15	88. 40	2. 8,4	6,5	7,6	14,0	6,8	8,1	+ 2,3	88. 42. 8,95	10. 25,07	10. 26,07
- 15	88. 30	1. 40,8	40,4	39,5	47,8	39,4	41,5	+ 1,8	88. 31. 41,87	10. 27,08	10. 26,11
+ 15	88. 40	2. 6,2	4,7	6,3	11,7	5,3	5,6	+ 2,3	88. 42. 7,02	10. 25,15	10. 26,97
- 15	88. 30	1. 39,0	38,5	37,6	46,0	38,4	39,0	+ 1,8	88. 31. 40,05	10. 26,97	

The correction for Runs found immediately after taking the above measures was $+5''.4$. The above differences of the concluded circle readings, being alternately greater and less than the mean of all, exhibit the effect of variable terrestrial refraction. This effect is very nearly eliminated in the differences obtained in the last column, the mean of which gives $10'.25''.90$ for the value of $30'$. Hence $1' = 20''.862$, which is adopted.

When an observation is not made at or very near the middle wire the distance of the place of bisection from the middle wire is stated in the *eleventh column* in whole intervals and parts of an interval between consecutive wires, the negative or positive sign being affixed according as the bisection was made before or after passing the middle wire. The times, as shewn by the Circle Clock Molyneux (M), of the bisection of Polaris or δ Ursæ Minoris, are inserted in the second column after the name of the star, and the difference between Molyneux and the Transit clock Hardy (H), is given in the notes at the bottom of the page.

To reduce an observation of a star to what it would have been if taken at the middle wire, a correction is required for curvature of diurnal path. This correction is calculated as follows. For Polaris or δ Ursæ Minoris, the time by Molyneux is converted into time by Hardy, and thence the true sidereal time is inferred from the error of Hardy given by the transit observations. The correction is then immediately deduced from the difference of this time and the time of meridian passage given in the Nautical Almanac, by means of Table III at the end of this Introduction. For other stars the correction is derived by interpolation from Table IV, which has been calculated by a known formula, according to which the correction for a given distance from the middle wire varies as the tangent of declination, and for a given declination, varies as the square of the distance. When the declination is 45° , the correction for one interval from the middle wire, which is traversed by an equatorial star in $16^s.6$, is $0''.1503$. Since in looking directly at an object between the pole and the equator the telescope is turned by reason of the curvature of path too far in the direction in which the graduation proceeds, the microscope readings are too small, and the correction is consequently positive. The contrary is the case below the equator and below the pole. In a reflection observation the error of position of the Telescope is in the opposite direction, and the sign of the correction is always contrary to that for the direct observation.

The formula for the calculation of corrections for curvature of path in the case of stars near the pole is,

$$\text{Correction} = [5,31445] \sin 2\Delta \sin^2 \frac{15t}{2},$$

Δ being the star's declination, and t the interval of the observation from meridian transit. The declination of Polaris being $88^\circ.29' + n''$, and that of δ Ursæ Minoris $86^\circ.35' + n''$, the formulæ used for the calculation of Table III are,

$$\text{Correction for Polaris} = [4,03802] \sin^2 \frac{15t}{2} - [0,30042] \sin^2 \frac{15t}{2} \times n,$$

$$\text{Correction for } \delta \text{ Ursæ Minoris} = [4,38991] \sin^2 \frac{15t}{2} - [0,29793] \sin^2 \frac{15t}{2} \times n.$$

The additional correction for change of N.P.D., required in observations of the moving bodies, when they are not taken on or near the meridian, has been calculated for the recently discovered Planets, by inferring the change in the interval between the time of observation and the passage across the middle wire, from the horary variation of N.P.D., known either from a working Ephemeris, or from the current observations. The computation of the correction is facilitated by the use of Table V at the end of this Introduction, which contains the values of the quantity,

$$\frac{16,6}{3600} \times \sec. \text{Decl}^n. \times \text{horary variation of Decl}^n.,$$

for declinations in integral degrees from 0° to 40° , and for horary variations in integral seconds from $1''$ to $10''$. As the corrections for the horary variations $0''.1$, $0''.2$, $0''.3$, &c., $20''$, $30''$, $40''$, &c. are obtained by merely changing the place of the decimal point, the Table gives the means of calculating by simple addition the corrections in any case for changes of N.P.D. in one interval from the middle wire. The amount of the correction required by the observation may then be deduced by multiplying the value for one interval by the number of intervals stated in the eleventh column.

The sign of the correction is determined from the circumstance that when the N.P.D. of the moving body is increasing, the Telescope is pointed for bisecting it too far in the direction of the Circle's graduation before it passes the middle wire, and after passage

too far in the opposite direction. The microscope readings require a *plus* correction in the former case, and a *minus* correction in the latter. If the N.P.D. is decreasing, the signs of the corrections are the contrary.

The *Pointer*, which is used for setting the Telescope to observe an object either directly or by reflection, a working catalogue of setting angles to the nearest minute being previously computed, is placed *below* microscope *A* at an interval of $10^{\circ}.45'$ nearly from the zero of its reading. The graduation proceeding in the direction from the microscope downwards, the pointer reading, (which is taken by sight), is the degrees and minutes of that division which in the order of graduation comes next before the position of the pointer. It has been thought unnecessary to place the pointer reading in a separate column, as it may be at once inferred from the concluded circle reading, the minutes being always an integral number of $5'$. As first set down, it is sometimes erroneous by a multiple of $5'$, but as the error is readily detected in the computations, no notice is taken of it in the notes.

The concluded circle reading in the *twelfth column* is the Pointer reading added to the mean of the microscope readings with all the above corrections applied. It is, therefore, the reading which would have been given by the circle, if the microscopes had been in accurate adjustment for runs, and the object had been bisected by the fixed wire at the middle vertical wire. For Polaris or δ Ursæ Minoris, the concluded reading applies to the time of meridian passage. If the circle were perfectly graduated, and always retained the circular form, and if the bisections of the divisions were accurately performed, different circle readings obtained in the manner just stated, would be comparable with each other though determined by a single microscope, provided also the zero of the microscope reading retained a fixed position relatively to the axis of the circle. Errors from imperfect graduation, inaccurate bisections, and deviation from the circular form, may be presumed to be corrected in great measure by the use of six microscopes, disposed at the opposite ends of diameters, and at equal intervals round the circle. It appears, however, that there is a residual inequality, which will be presently noticed.

The circle reading corresponding to the position of the Telescope when directed exactly to the zenith is called the *Zenith Point*. The adopted zenith point throughout the year 1849 was obtained by the collimating eye-piece used in the manner explained in page iii. The micrometer reading for coincidence of the micrometer wire with its image was first deduced from at least six readings for coincidence, or for alternate contact, and the concluded circle reading for the zenith direction was calculated, just as if the image had been a celestial object in the zenith observed by reflection. The zenith point is generally taken in this manner once a week, and the result is used from the third or fourth day previous.

The microscope readings for the determination of the zenith point are inserted among those for the observations of the celestial objects named in the second column. For greater accuracy the microscopes were read twice, but the mean of the two sets of readings is alone inserted. The concluded circle reading obtained by reducing an observation of zenith point in the same manner as the other observations are reduced, when increased by 180° is in general the adopted zenith point. The limits within which any value is used are indicated by bars across the column of "concluded circle readings." If two observations of zenith point occur within the same limits, the value used is the mean between the two results.

The following is a list of the seconds of all the zenith points taken in 1849, with the approximate mean times at which they were taken. The degrees and minutes were $291^{\circ}.39'$ to the end of February, and $358^{\circ}.42'$ subsequently, the Telescope having been shifted on the limb of the circle on March 1. On that and the following day the Circle was taken from the wall to clean its axis, the microscopes

were adjusted, and the micrometer-wire was placed so as to be traversed by an equatorial star. Also on Aug. 22 the axis was cleaned and the microscopes were adjusted. By inadvertence these notices are omitted in the Notes.

Zenith Points obtained in 1849 with the Collimating Eye-piece.

Time of Observation.	Seconds of Zenith Point.	Time of Observation.	Seconds of Zenith Point.	Time of Observation.	Seconds of Zenith Point.

The zenith point used on Jan. 2 and 5 is that obtained on Dec. 20, 1848. Those taken on April 3, May 14, Aug. 23 and Dec. 24, were not required in the reduction of the observations. Between June 14 and July 11 Circle observations were suspended. The mean of the two zenith points obtained on Sept. 4 by different observers is used from Sept. 4 to Sept. 12. It may be remarked that values obtained by different observers at nearly the same time exhibit a satisfactory accordance: also that there is a tendency to a maximum of value at the hottest part of the year.

The apparent zenith distance, in the direct observation of any object, is the algebraic excess of the concluded circle reading above the adopted zenith point, and for a reflection observation it is the algebraic excess of the nadir point above the concluded circle reading. The object is North or South of the zenith according as the excess is in either case positive or negative. The apparent zenith distance thus obtained is used with the data in the three next columns for the calculation of *refraction*.

The *thirteenth column* has the height of the barometer as shewn by a cistern-barometer constructed by Dollond, and attached to the circle pier. The lower surface of the mercury is raised by a screw pressing the bag till the light seen below a brass edge is excluded; and a brass slider is brought to the upper surface to shut out the light in the same way. As it appeared by a comparison of this with six other barometers (the particulars of which are given in the volume for 1835, p. xxxi) that its readings were too small by 0,1 inch nearly, the height immediately read from the barometer, which is that recorded in the thirteenth column, is always increased by that quantity in calculating the refraction.

The *fourteenth column* has the reading of the thermometer whose bulb is plunged in the cistern of the barometer.

The *fifteenth column* contains the reading of an external thermometer, which is fixed to a stage near the north shutter-opening at a distance of four feet from the wall of the building and nine feet from the ground. It is protected from radiation and the weather, and contiguous parts of the building prevent the direct rays of the Sun falling upon it.

The refraction is calculated by Bessel's tables, (*Tabulæ Regiomontanæ*, p. 538, &c.) by making use of the Appendix to the *Greenwich Observations* of 1836. In this mode of calculating the reading of the attached is supposed to be the same as that of the external thermometer. The former reading, though not made use of, is inserted in the printed columns, to allow of correcting, if thought necessary, for the error of this supposition.

By adding the refraction to the apparent zenith distance North or South, the true zenith distance is found, and by adding algebraically the true zenith distance, considered negative when north of the zenith, to the assumed co-latitude of the observatory, viz. $37^{\circ}.47'.8''.00$, the Apparent N.P.D. from the observation, given in the *fifteenth column*, is obtained. The result is, therefore, the North Polar Distance of the object named in column 2, at the time of its passing the middle wire, affected, in the case of a body of the Solar System, by *parallax*, and in every case, affected by uncorrected instrumental errors and errors of observation, as also by any errors in the assumed values of the constants employed in the calculations.

The *last column* contains the initial of the observer's name. The letter C indicates that the observation was taken by myself, the Italic *C* that it was taken by Mr Carrington, and the letters B and T indicate that the observations were taken respectively by Mr Breen and Mr Todd.

IV. *Mean North Polar Distances, Jan. 1, 1849, of Stars, as deduced from the observations of each day.*

The columns in pages 84—96 contain the names of the stars in order of Right Ascension, the days on which each star was observed, the corrections to be applied to the apparent N.P.D. already calculated, to obtain the mean N.P.D., and the resulting mean N.P.D. Jan. 1, 1849, given by each day's observation. The results by the same star, when observed above, and when below the pole, are arranged separately to serve for correcting the assumed co-latitude. Also, the results by direct observations are separated from those by reflection observations of the same star, for the purpose of exhibiting the effect of the discordance of zenith points spoken of hereafter, and furnishing data for applying a correction.

The corrections applied to the apparent N.P.D. are obtained as follows. For stars included in the list of the Nautical Almanac, the corrections are the algebraic excesses of the apparent above the mean declinations of that work, South declinations being considered negative. For stars not in the Nautical Almanac, but included in the Catalogue of the British Association, the correction $\delta\Delta$ is calculated by the formula

$$-\delta\Delta = Aa' + Bb' + Cc' + Dd'.$$

$\log A$, $\log B$, $\log C$, $\log D$, being taken from the Nautical Almanac, and $\log a'$, $\log b'$, $\log c'$, $\log d'$, from the Catalogue. For stars not in that Catalogue, the corrections are calculated by the following formula, depending on the expressions for a' , b' , c' , d' , given in p. xvii of the Preface to the Catalogue of the Royal Astronomical Society.

$$\begin{aligned} \text{Correction} = & A \times (\text{No. log} = 9,6375) \times \sin \text{N.P.D.} - A \sin \text{R.A.} \cos \text{N.P.D.} \\ & + B \cos \text{R.A.} \cos \text{N.P.D.} + C \times (\text{No. log} = 1,3020^*) \times \cos \text{R.A.} - D \sin \text{R.A.} \end{aligned}$$

A Catalogue of the concluded Mean R.A. and concluded Mean N.P.D. Jan. 1, 1849, of the Stars observed in 1849, with the Annual Variations, is given in pages 98—115. The concluded mean R.A. is the mean of all the separate R.A. in pages 42—60, and the concluded mean N.P.D. is the mean of the separate N.P.D. contained in pages 84—96, corrected for the discordance of zenith points and for the error of the assumed co-latitude, in the manner about to be explained. The results in brackets are not taken into account in calculating the concluded mean. When a star has been observed only with the Transit, its approximate N.P.D. to the nearest minute is placed in the column of concluded N.P.D.,

* The value of this constant for 1849 is more correctly 1,3022.

and when observed only with the Circle, the approximate R.A. to the nearest second is placed in the column of concluded R.A.

The *Annual Variations* in R.A. and N.P.D. are either taken from the Nautical Almanac, or are computed by the following formulæ, the constants of which are derived from p. x of the *Tabulæ Regiomontanæ*:

$$\text{Annual Variation in R.A.} = 3^{\circ}.0706 + [0,12613] \sin \text{R.A.} \cotan \text{N.P.D.}$$

$$\text{Annual Variation in N.P.D.} = -[1,30222] \cos \text{R.A.}$$

Proper motions are not taken into account unless they are included in the Annual Variations adopted from the Nautical Almanac.

The column of 'observed magnitudes' contains the means of estimations of magnitude made at the separate observations, whether with one or with both instruments, as often as the observers recorded them. Several of these estimations appear to have been affected by atmospheric circumstances. In case the star is not in Catalogues, and the magnitude was not noted at any of the observations, the magnitude as derived from observations of former years, or from equatorial observations made expressly for the purpose, is put in the column containing the names of the stars. This is done to facilitate the identifying of these stars.

When the star is double, the component to which the concluded R.A. and N.P.D. apply is indicated by the letters *np*, *nf*, *sp*, *sf*, in their usual signification. It is presumed, if the observer has not noted which star was taken, and the components are known to be far enough apart to be seen distinctly in the Transit and Circle Telescopes, that the selection has been made according to the rule in p. i. Also if the star has not been distinguished as double, and one of the components is known to be much brighter than the other, the observations are considered to apply to the brighter. In several instances of very close components of nearly equal magnitude, no letters are affixed, and the R.A. and N.P.D. are supposed to apply to the middle point between them.

The 'Notes' in the last column contain incidental remarks, chiefly relating to the identifying of the stars and estimations of magnitude, and to the rectification of errors in Catalogues.

The correction for the error of the assumed co-latitude, is derived from a determination of the co-latitude of the Observatory, calculated from all the observations of the same stars above and below pole which were made in the years 1836, 1837, and 1838. The calculation is given in pages liii—lviii of the Introduction to the Volume of 1838, and the result is, that the assumed co-latitude $37^{\circ}.47'.8''.00$ should be corrected by $+0''.37$. This quantity is accordingly added algebraically to the mean N.P.D., considering them negative when the stars are observed below the pole.

The correction for discordance of zenith points is applied on the following principle. When the mean between the two concluded circle readings for the reflection and direct observations of the same star at the same transit, is increased or diminished by 90° , the result is the zenith point given by those observations. On comparing zenith points thus obtained by stars of different N.P.D., the values are found to be slightly discordant: on which account the observation of stars by reflection has been continued at the same time with the use of the collimating eye-piece, for the purpose of obtaining data for applying corrections. The discordance is of such a nature, that the circle reading for zenith point is in general less by a star observed south of the zenith than by a star observed north of the zenith. Apparently when the object-glass is to the south of zenith, the Telescope, whether directed to the heavens or the trough of mercury, requires to be turned for bisecting an object, a little farther in the direction of the graduation, than

if the cause of inequality did not exist; and when the object-glass is to the north of zenith, a little in the contrary direction. Whatever may be the cause of the discordance, the error it produces may be presumed to be corrected by reducing the different zenith points to the zenith point corresponding to a *given* zenith distance. The collimating eye-piece gives correctly the zenith point corresponding to the zenith direction. Hence, if M be the adopted zenith point employed in the calculation of the apparent N.P.D., and Z the zenith point resulting from a particular double observation south of zenith, $M-Z$ is the error of the circle reading in defect, both for the reflexion and the direct observation, supposing both to be equally affected by the inequality. By this quantity the N.P.D. is too small as determined by the direct observation, and too great as determined by the reflection observation; so that the algebraic excess of the latter determination above the other is twice $M-Z$. This rule applies to observations north of the zenith, by taking the N.P.D. negative when the star is observed below the pole. The following table exhibits for each star observed directly, and by reflection, the mean value of $M-Z$, derived from the lists in pages 84—96 by halving the algebraic excess of the mean of the N.P.D. by reflection above the mean of the corresponding N.P.D. by direct vision.

Mean Excess for each Star of the adopted Zenith Point above the Zenith Points given by observation in 1849.

From the foregoing table the corrections to be applied to N.P.D. observed directly were deduced as follows. The above mean values of $M-Z$ were divided into groups the limits of which (indicated by the lines across) were chosen so that the stars of each group do not greatly differ in zenith distance. Each mean value in the group was multiplied by the number of observations by which it was determined, and the corresponding zenith distance by the same number. The sum of each series of products being divided by the whole number of observations in the group, the resulting value of $M-Z$ was considered to belong to the resulting zenith distance. A line of abscissæ was then

drawn on which these zenith distances were set off, and the corresponding values of $M-Z$ being taken for ordinates, a curve was traced by hand among the points thus laid down, so as to approach nearer to any point, the greater the number of observations by which its position was determined. Ordinates of this curve were then measured at intervals of 5° , and the measures with the corresponding N.P.D. were tabulated, to serve for obtaining by interpolation the correction for any proposed N.P.D. From what has already been said, the sign of the correction for a direct observation is the same as that of $M-Z$, or the ordinate of the curve, and for a reflexion observation, the contrary sign. In the subjoined table the correction $+0''.37$ for error of assumed co-latitude is included.

Corrections for Discordance of Zenith Points and Error of the assumed Co-latitude, applied to N.P.D. obtained by direct and reflection observations in 1849.

N.P.D.	Correction to direct observation.	Correction to reflection observation.	N.P.D.	Correction to direct observation.	Correction to reflection observation.	N.P.D.	Correction to direct observation.	Correction to reflection observation.
0	"	"	40	$+0.15$	$+0.59$	85	$+0.81$	-0.07
$-1\frac{1}{2}$	-0.80	$+1.50$	45	$+0.67$	$+0.07$	90	$+1.04$	-0.30
0	-0.83	$+1.57$	50	$+1.02$	-0.28	95	$+1.17$	-0.43
$+5$	-0.89	$+1.63$	55	$+1.17$	-0.43	100	$+1.23$	-0.49
10	-0.95	$+1.69$	60	$+1.17$	-0.43	105	$+1.26$	-0.52
15	-0.98	$+1.72$	65	$+0.99$	-0.25	110	$+1.26$	-0.52
20	-0.96	$+1.70$	70	$+0.53$	$+0.21$	115	$+1.24$	-0.50
25	-0.87	$+1.61$	75	$+0.31$	$+0.43$	120	$+1.22$	-0.48
30	-0.68	$+1.42$	80	$+0.42$	$+0.32$			
35	-0.28	$+1.02$						

The observations from which the above Table was formed are perhaps hardly sufficient in number: the law and the amount of discordance are, however, nearly the same as in former years. The zenith direction as given by the collimating eye-piece is apparently $+0''.41$ more *southward* than the direction as given by reflection observations of stars.

V. *Approximate R.A. and N.P.D. of Zodiacal Stars observed with the Mural Circle*

Pages 118—134.

This series of observations was undertaken with the view of forming as complete a Catalogue as possible of the stars to the ninth magnitude inclusive, contained within a zone extending 5° on each side of the ecliptic, and to determine their places with a sufficient degree of accuracy for use in equatorial observations of the Minor Planets. It was, however, found after a trial of above two months that the Mural Circle could not be depended upon for accurate determinations of Right Ascensions even through a small arc of the meridian, apparently on account of displacements by clamping for the observations of N.P.D., and in part probably from the form of the pivot. This kind of observation, which requires the use of a Transit Circle, was consequently abandoned, and a working list of Zodiacal Stars included within the above-mentioned zone, was formed from the Catalogue of the British Association, Weisse's Reduction of Bessel's Zones, and Baily's Reduction of the *Histoire Céleste*, to be observed with both instruments. A large proportion of the objects observed on the meridian in 1849 consists of stars of this list. It was, however, thought worth while to reduce and publish the zone observations taken with the Mural Circle, as they embrace a considerable number of stars not in Catalogues, and give places which, though not uniformly accurate, are always approximately true. The following is an account of the reduction of these observations.

The intervals between the vertical wires were calculated from eight complete transits of Polaris SP taken from March 29 to June 4, from which the following Table of the intervals of the wires from the mean of all was formed:

	Equatorial Interval.	Polaris. Decl ⁿ . = $88^{\circ}.30' + n''$.
<i>a</i>	-32,824	-20.55,67 - 0,233 <i>n</i>
<i>b</i>	-16,441	-10.28,27 - 0,116 <i>n</i>
<i>c</i>	-0,089	-3,41 - 0,001 <i>n</i>
<i>d</i>	+16,468	+10.29,31 + 0,117 <i>n</i>
<i>e</i>	+32,886	+20.58,04 + 0,234 <i>n</i>

Stars above the pole cross the wires in the order *abcde*. By means of this Table imperfect transits were reduced to the mean of the five wires in the usual manner.

The collimation, level, and azimuth errors were first obtained roughly as follows. For the calculation of level error the transit of Polaris observed directly at the second wire on March 30, was compared with the transit observed by reflection at the same wire on March 31. If t_1 = the first time, t_2 = the second, δ = the star's N.P.D., and L = the latitude of the Observatory, then by a known formula,

$$\text{Correction for level error} = + \frac{15}{2} (t_2 - t_1) \sin \delta \operatorname{cosec} (L + \delta).$$

By calculation from this formula it was found that the East end of the axis was too high by $10''.4$.

To find the collimation error of the middle wire, the Telescope was directed to the Nadir and the image of the wire was seen by reflection at the surface of mercury. There being no micrometer wire parallel to the middle wire, the interval between the middle wire and its image was obtained approximately by making the interval between the micrometer wire and its image to be by estimation the same. The half of this interval was found to be $1^r.375$ in micrometer revolutions, which in arc is $28''.7$, the value of one revolution being $20''.86$. As the image of the middle wire was *Westward*, the middle wire deviated from the meridian eastward by $28''.7$: and as the level error caused a deviation westward of $10''.4$, it follows that the wire-frame was too much eastward by $39''.1$.

The azimuth error was calculated from the observations of Polaris SP March 29, and Polaris March 30 and 31 in the usual manner, after correcting for collimation and level errors, and it was found that the west end of the axis was too much northward by $27''.4$.

On April 3 an attempt was made to correct the level and azimuth errors by turning the screws of the West pivot, and then to correct the collimation error by shifting the wire-frame so as to make the middle wire and its image coincide. But partly from a mistake in the calculation of azimuth error, and partly from uncertainty as to the amount of correction produced by turning the screws, the desired corrections were not effected, as appeared by the subsequent reduction of the observations, and in consequence the instrumental errors remained of large amount during the whole of the series.

The following instrumental errors were determined from observations made after the adjustments on April 3. By comparing the direct transit of Polaris SP on April 3 with the reflection transit on April 7, allowance being made for the rate of the clock (Molyneux) and the change of the star's R.A., the level error was found by the foregoing formula to be $+18''.74$. A like comparison of the direct transit of Polaris SP on April 5 (reduced to the mean of the wires) with the reflection transit of April 7, gives $+19''.12$. Taking the mean of these values, viz. $+18''.93$, for level error, since the middle wire and its image were placed in coincidence on April 3, the collimation error of the middle wire from that date is $-18''.93$. As the mean of the wires is more eastward by $1''.34$ than the middle wire, the concluded collimation error, inclusive of $-0''.18$ for diurnal aberration, is $20''.5$.

The level errors given by the direct and reflection transits of Polaris April 26 and 29, those of Polaris SP May 29, May 31, and June 1, and those of Polaris SP June 2 and 4, are respectively $+17''.9$, $+20''.1$, and $+17''.7$. Making use of the several determinations of level error, and assuming the collimation error to be $-20''.5$ throughout, the following are the values of the azimuth error found by the usual processes.

Days of Observation.	Stars employed.	Azimuth Error.	Days of Observation.	Stars employed.	Azimuth Error.
April 3 ...	Polaris SP and Spica	... -43,4	May 15 ...	Polaris SP and Spica	... -43,5
5 ...	—————	... -44,3	15 and 16 ...	Polaris SP and Polaris	... -42,9
7 ...	—————	... -43,9	29 ...	Polaris SP and Spica	... -41,6
26 ...	—————	... -42,3	June 1 and 2 ...	{ Polaris SP, Polaris and Polaris SP }	... -43,4
26 ...	Polaris SP and Polaris	... -43,8			
May 3 and 4 ...	{ Polaris, Polaris SP, and Polaris }	... -41,7			

The foregoing discussion of the instrumental errors shews that the circle was sufficiently steady during the whole series of observations. It was, however, found that the values thus obtained for errors of collimation, level and azimuth did not give accordant clock-errors of the fundamental stars, and it was impossible to say whether the discordances were due to the form of the East pivot, or the strain on the instrument caused by clamping, or to errors of 1^s in counting. On this account it was judged to be most accurate to infer the corrections for reduction to the meridian and clock-error conjointly for the known stars on each day from their known R.A., and to deduce the like corrections for unknown stars by interpolation, the clock's rate being taken into account.

These corrections of the transit-time for the known stars are placed in the ninth column (pages 118—126), and the mean of them on any day (exclusive of those for Polaris) is considered to apply to the mean of the times of observation and the mean of the N.P.D. of the stars. The clock's rate in the tenth column has been always deduced from comparisons of transits of the *same* star on different days, and the hourly correction in the eleventh column is the rate divided by 24, with the negative sign attached because the clock had a gaining rate. This hourly correction, multiplied by the algebraic excess of the time of transit of an unknown star above the time corresponding to the mean correction, gives the quantity to be added to the mean correction to obtain the correction of transit-time for that star, so far as it depends on the clock's rate. The correction depending on N.P.D. was obtained by dividing the clock-stars observed on any day into a northern and a southern group, and finding for each group a mean correction corresponding to a mean time and a mean N.P.D. The two mean corrections were then corrected for clock's rate to the same mean time, and the excess of that for the southern above that for the northern group, being divided by the difference of the two mean N.P.D. in degrees, is the quantity put in the twelfth column. This quantity, multiplied by the algebraic excess in degrees of the N.P.D. of the unknown star above the mean of the N.P.D. of all the known stars, gives the additional quantity to be applied to the mean correction. The correction resulting from the application of the two quantities is the 'Correction of transit-time' in the thirteenth column, which added with its proper sign to the transit-time gives the star's apparent R.A.

Discordant clock-errors frequently occurred in Mr Todd's observations of Spica when followed by observations of Polaris SP, as on May 31 and June 1, 2 and 4. The observation of June 11, which was not preceded by one of Polaris SP, presents no such discordance. It was not possible to decide whether the discordance was due to the sudden change of position of the Circle in passing from the transit of Polaris at wire IV to the transit of Spica at wire V, the interval being only 47^s, or to an error of 1^s in counting caused by the hurry of the observation. As Mr Todd's transits exhibit many such errors it was thought that the latter is the most probable explanation, and accordingly the observations on the days above-mentioned have been altered.

On several days the clock-errors could not be divided into a northern and a southern group, being either too few in number, or not appropriately distributed. In these instances the time-corrections for difference of N.P.D. (in column 12) are taken from those immediately preceding or following. Thus the corrections adopted on April 14, April 28, May 7, May 23, are the same as those next preceding; that on June 8 is the same as the following one determined on June 9; the value used on April 30 and May 2 is the mean of the results obtained on April 26 and May 3; and on June 11 and 13 the value adopted is the mean between determinations made on the two days. On May 23 κ Virginis is used as a clock-star, its apparent R.A. viz. $14^h.4^m.52^s.75$ being calculated from the Greenwich 12-year Catalogue.

The calculations relating to the observations of the apparent N.P.D. of Zodiacal Stars in pages 127—134 require no explanation, being exactly the same as for the other Circle observations, with the exception that as two microscopes only were used, the zenith points and corrections for Runs were inferred exclusively from readings of those microscopes.

The *Catalogue of the concluded Mean R.A. and concluded Mean N.P.D. of the Zodiacal Stars* in pages 136—142 was formed in the same manner as the general Catalogue, excepting that the result of each observation of the same star stands separately. The column of 'observed magnitudes' contains only such magnitudes as were noted at the time of observation.

VI. *Right Ascensions and North Polar Distances of Planets observed in 1849, with the Greenwich Mean Solar Times of observation.* Pages 144—146.

The *Right Ascensions* were taken immediately from the previous part of the work. The *Geocentric North Polar Distances* were deduced from the observed apparent N.P.D. by applying corrections for parallax, and for the discordance of zenith points with the error of assumed colatitude. The correction for parallax was calculated as follows. If r and D be respectively the lines from the centre of the Earth to the place of observation and object observed, α the angle they make with each other, r' the Earth's equatorial radius, D' the mean distance of the Sun from the Earth, and p the parallax, then $p = \frac{r}{r'} \times \frac{r'}{D} \times \frac{D'}{D} \sin \alpha$. $\text{Log } \frac{r}{r'}$ is taken = 9,9990916, which supposes the ratio of the Earth's axes to be that of 297 to 298; $\log \frac{r'}{D} = 0,9333658$, the assumed value of the Sun's equatorial horizontal parallax at the mean distance being $8''.5776$; $\log \frac{D'}{D}$ is the arithmetical complement of log. distance given by theoretical calculation; and α is found by subtracting $11'.12''$, the angle of the vertical corresponding to the above ratio of the axes, from the observed zenith distance.

The *Greenwich Mean Solar Times* were calculated by adding to the equivalent in mean time of the sidereal time of transit, the next preceding mean time of transit of the first point of Aries, diminished by $22^s,69$, the longitude of the Cambridge Observatory being $22^s,75$ East of Greenwich, according to a new determination made in 1853 by Galvanic signals, the particulars of which are published in the Transactions of the Cambridge Philosophical Society, Vol. IX. Part IV.

In all the instances in which Circle observations were not accompanied by Transit observations, the Greenwich Mean Times were deduced from the Tabular R.A., as given by Ephemerides, or obtained by special calculation, corrections being applied for the errors of the Tables in R.A.

The Tabular R.A. and N.P.D., and the Equatorial Horizontal Parallax of Flora were interpolated from Dr Brünnow's Ephemeris in the Monthly Notices of the Royal Astronomical Society, Vol. IX. p. 154.

The Tabular R.A., N.P.D., and Log. distance of Iris were calculated for the respective Greenwich Mean Times, from Schubert's Elements in Vol. XXVIII column 285, of the *Astronomische Nachrichten*. These elements were used at first as applying to the beginning of the year, but the epoch being found to be a day earlier, the mean anomaly was increased by $962''.9$, and the Elements actually employed are the following :

Mean Anomaly 1849,0 Berlin Mean Time	68 . 45 . 13,27	} Mean ΔEq^x . 1849,0.
Longitude of Perihelion	41 . 30 . 7,93	
Longitude of Ascending Node	259 . 45 . 59,17	
Angle of Eccentricity	13 . 22 . 46,31	
Inclination	5 . 28 . 11,36	
Logarithm of Mean distance	0,3777841	
Daily increment of Mean Anomaly	962,34433	

In calculating the corrections for aberration Schubert's Ephemeris in No. 666 of the same work was used for finding the rates of change of R.A. and N.P.D.

The Tabular R.A., N.P.D. and Log. distance of Metis were interpolated from Graham's Ephemeris in Vol. XXIX. No. 684, and Vol. XXX. No. 697, of the *Astronomische Nachrichten*; and those of Hebe from Luther's Ephemeris in Vol. XXVIII. No. 656.

The Tabular R.A., N.P.D. and Log. distance of Astræa were interpolated from the Ephemeris in the *Berliner Jahrbuch* for 1852, p. 385, for the observations in October and November, and for the remainder were calculated from D'Arrest's Elements in Vol. XXX. No. 704 of the *Astronomische Nachrichten*, which are those used for the calculation of the Ephemeris: viz.

Mean Anomaly 1849, Nov. 10,0 Berlin Mean Time	294 . 19 . 42,35
Longitude of Perihelion	135 . 42 . 29,4
Longitude of Ascending Node.....	141 . 27 . 24,7
Angle of Eccentricity	10 . 50 . 56,5
Inclination	5 . 19 . 26,8
Logarithm of Mean distance	0,4110398
Daily increment of Mean Anomaly	857'',92023

It being ascertained that the Ephemeris did not include aberration, corrections on that account have been applied to the interpolated R.A. and N.P.D. The aberration corrections for the calculated R.A. and N.P.D. were obtained by first finding from the approximate Ephemeris in p. 384 of the *Berliner Jahrbuch* the rates of change of R.A. and N.P.D. Also from a calculation of the Planet's place for Nov. 27,5 Berlin Mean Time, it appeared that the resulting R.A. and N.P.D. required respectively the corrections $+0^s,04$ and $+0'',51$ to make them agree with those of the Ephemeris, owing probably to some difference in the constants employed. These corrections have consequently been applied to our calculated R.A. and N.P.D. to reduce them to uniformity with those of the Ephemeris. The calculated N.P.D. for the Circle observation of Dec. 29 shewed that the object observed was not the Planet.

The Tabular R.A., N.P.D. and Log. distance for Neptune were interpolated from Walker's Ephemeris as given in the *Astronomische Nachrichten*, Vol. XXIX. No. 676.

VII. *Occultations of fixed stars by the Moon, and Calculation of the Equations given by the Occultations.* Pages 148—161.

The sidereal times of the phænomena were derived from the noted times by means of the comparisons in page 148, and the Greenwich Mean Solar Times were calculated in the manner already stated. For the calculation of the occultations, the geocentric R.A. and N.P.D. of the Moon's centre, the Horizontal Equatorial Parallax, and the Geocentric Semidiameter, were interpolated for the time of observation with second differences from the Nautical Almanac, whence also the assumed R.A. and N.P.D. of the stars were taken. The Moon's apparent R.A., N.P.D., and semidiameter, the apparent distance of the star from the Moon's centre, and the coefficients of small variations, were calculated by the formulæ in the Appendix to the Nautical Almanac for 1854, which are for the most part the same as those given in pages xxxiii and xxxiv of Vol. XIII of the Cambridge Observations. The former take into account any error (ν) of the assumed geocentric colatitude of the Observatory by the following equations:

$$\text{coefficient of } \nu \text{ in } \delta R = \sin \theta \operatorname{cosec} \theta' \cot l \sin (\theta - \theta'),$$

$$\text{coefficient of } \nu \text{ in } \delta \lambda = -R' \frac{\sin \theta}{\sin \theta'} \cdot \frac{\sin \lambda}{\sin \lambda'} (\cos \lambda \cos l \cos \theta + \sin \lambda \sin l),$$

in which θ is the apparent hour angle of the Moon's centre, θ' the geocentric hour angle,

λ the apparent N.P.D., λ' the geocentric N.P.D., l the assumed colatitude $37^{\circ}.58'.20''$, 37 , and F is the sine of the horizontal parallax. The angle of the vertex and the ratio of the distance of the Observatory from the Earth's centre to the Equatorial radius, have been computed on the supposition that the ratio of the latter to the Polar radius is that of 298 to 297.

OBSERVATIONS OF 1850.

The explanation of the printed observations being generally the same for 1850 as for 1849, it will only be necessary to advert here to what is peculiar to the former year, and to give an account of the constants employed in the reduction of the observations.

I. *Apparent Right Ascensions observed with the Transit.* Pages 164—204.

The following Table of intervals of the wires from the mean of all, which was used throughout 1850, was computed from nineteen complete transits of Polaris, six of which were taken in 1849, eleven in 1850, and two in 1851. During these three years the intervals remained steady, and were nearly the same as in 1848.

Wire.	Interval for an Equatorial Star.	Interval for Polaris. Declination = $88^{\circ}.30' + n''$.	Interval for δ Ursæ Minoris. Declination = $86^{\circ}.35' + n''$.
	<i>s.</i>	<i>m.</i> <i>s.</i> <i>s.</i>	<i>m.</i> <i>s.</i> <i>s.</i>
A	- 40,344	- 25 . 44,43 - 0,287 <i>n</i>	- 11 . 17,22 - 0,055 <i>n</i>
B	- 26,892	- 17 . 8,29 - 0,191 <i>n</i>	- 7 . 31,32 - 0,037 <i>n</i>
C	- 13,573	- 8 . 38,63 - 0,096 <i>n</i>	- 3 . 47,76 - 0,019 <i>n</i>
D	- 0,060	- 2,29	- 1,01
E	+ 13,618	+ 8 . 40,34 + 0,096 <i>n</i>	+ 3 . 48,51 + 0,019 <i>n</i>
F	+ 26,913	+ 17 . 9,09 + 0,191 <i>n</i>	+ 7 . 31,67 + 0,037 <i>n</i>
G	+ 40,337	+ 25 . 44,18 + 0,287 <i>n</i>	+ 11 . 17,10 + 0,055 <i>n</i>

The intervals for the Sun and Planets are calculated from the intervals for an Equatorial star, by multiplying by the cosecant of N.P.D. and by the factor $1 + \frac{I}{3600}$, the horary variation (I) of the R.A. being either taken from the Nautical Almanac, or inferred from the R.A. observed on different days. The multiplier for the Moon, which takes account of the variation of R.A. as affected by parallax, is calculated from the expression

$$\frac{3600 + I}{3600} \times \frac{\sin \text{Moon's geocentric Zen. Dist.}}{\sin \text{Moon's apparent Zen. Dist.}} \times \text{cosecant of N.P.D.,}$$

where I is the increase of the Moon's R.A. in passing over 1^h of terrestrial longitude, given under the head of Moon-culminating stars in the Nautical Almanac.

Corrections have been applied for the forms of the Transit pivots in the reduction of the observations of 1849 (see p. vii), and in those of former years. But as the methods employed for ascertaining these corrections were imperfect, depending on the use of the Spirit Level only, I adopted in 1850 another method the principle of which is as follows.

The angular position of the straight line joining two points, situated at the ends of the pivots near the axis of motion, and rigidly connected with the instrument, was ascertained for various zenith distances by measures of their vertical and meridional horizontal co-ordinates made by two microscope-micrometers. This angular position is geometrically connected with the angle which an adopted line of collimation makes with the plane of the meridian, and the latter may be calculated from the former, when the numerical values of three constants involved in the analytical formula have been ascertained.

The instrumental operations for finding the constants are exactly the same as those by which the collimation, level, and azimuth errors are found on the supposition of equal and cylindrical pivots. Hence the reduction to the meridian for the position of the Transit may be calculated in two ways from the same data, and the results for a given zenith distance ought to agree if the pivots were really equal and cylindrical. The differences between the results may be attributed to the form and relative size of the pivots. These differences being ascertained at any date for zenith distances increasing by a given interval, may be assumed to be constant during the year preceding and the year following, and their values for any zenith distances may be found by interpolation.

A description of the manner of using the microscope-micrometers for the purpose above-mentioned, and an investigation of the general formula for the angular deviation (ξ) of the line of collimation from the plane of the meridian, with the methods of determining the three constants which the formula involves, are given in detail in the Memoirs of the Royal Astronomical Society, Vol. XIX. p. 103, to which I beg to refer for further information. The formulæ used for the reduction of the Transit observations of 1850 were obtained as follows.

The general formula for the value of ξ is,

$$\xi = d + (f_2 y_2 + k - f_1 y_1) \cos z + (g_2 x_2 + h - g_1 x_1) \sin z,$$

in which y_1, y_2 are the micrometer readings for bisection of the east and west points respectively by the micrometer wires placed horizontally, and x_1, x_2 are the micrometer readings for bisection of the same by the wires placed vertically: f_1, f_2, g_1, g_2 are factors by which the micrometer readings are converted into seconds of arc: $f_1 y_1, f_2 y_2 + k$ are the vertical ordinates of the points in seconds referred to the same horizontal plane, and $g_1 x_1, g_2 x_2 + h$, are the horizontal ordinates referred to the same vertical plane perpendicular to the meridian, the former being reckoned positive upwards, and the latter positive towards the south: d is a constant which has a different value according as the Illumination is East or West, and z is the Zenith Distance South.

For finding the factors f_1, f_2, g_1, g_2 , two circles are engraved about the points, or dots, bisected by the micrometer wires, the diameter of that at the Illumination end of the axis being $0^{\text{in}}.0465$, and the diameter of the other $0^{\text{in}}.0458$. The distance between the dots being ascertained by measurement, the angles subtended by the diameters at the dots, that is, the angular measures of the diameters, are known. The factor to be used for converting a micrometer reading of either microscope into angular measures for a given position of the Transit, is found by dividing the angular measure of the diameter of that circle which surrounds the dot bisected, by its measure in micrometer revolutions.

Let d_e and d_w represent the values of d for Illumination East and West respectively. Then supposing ξ to be positive if the line of collimation points to the *East* of the meridian, the value of ξ , when the Telescope is directed to the Nadir, is $-a$, or $-b$ according as the Illumination is East or West. (See p. iii). Let $F_2 Y_2 + k, F_1 Y_1$, be the vertical co-ordinates of the West and East dots, the Telescope pointing to the Nadir and Illumination West, and $F'_2 Y'_2 + k, F'_1 Y'_1$, the like co-ordinates for Illumination East. Then putting 180° for z , we shall have from the general formula,

$$\begin{aligned} -a &= d_w - F_2 Y_2 - k + F_1 Y_1 \\ -b &= d_e - F'_2 Y'_2 - k + F'_1 Y'_1. \end{aligned}$$

Again, if θ be the constant angle which the direction of collimation makes with the line joining the dots, in one position of the instrument $\theta = 90^\circ - a +$ the angular elevation of the West end of that line, that is

$$\theta = 90^\circ - a + F_2 Y_2 + k - F_1 Y_1,$$

and in the reverse position $180^\circ - \theta = 90^\circ - b + F'_2 Y'_2 + k - F'_1 Y'_1$.

Hence we obtain a third equation,

$$0 = -a - b + F_2 Y_2 - F_1 Y_1 + F'_2 Y'_2 - F'_1 Y'_1 + 2k.$$

Putting for brevity Y_w for $F_2 Y_2 - F_1 Y_1$, and Y_e for $F'_2 Y'_2 - F'_1 Y'_1$, the three equations give

$$\begin{aligned} k &= \frac{a + b}{2} - \frac{Y_w + Y_e}{2}, \\ d_e &= -d_w = \frac{a - b}{2} - \frac{Y_w - Y_e}{2}. \end{aligned}$$

Hence the general formula becomes

$$\xi = \pm \left(\frac{a-b}{2} - \frac{Y_w - Y_e}{2} \right) + \left(f_2 y_2 - f_1 y_1 + \frac{a+b}{2} - \frac{Y_w + Y_e}{2} \right) \cos z + (g_2 x_2 - g_1 x_1 + h) \sin z,$$

according as the Illumination is East or West. And if ξ_1 be the value that would be obtained for ξ on the supposition of equal and cylindrical pivots,

$$\xi_1 = \pm \frac{a-b}{2} + \frac{a+b}{2} \cos z + c \sin z,$$

c being the azimuth error. Hence

$$\xi - \xi_1 = \pm \frac{Y_e - Y_w}{2} + \left(f_2 y_2 - f_1 y_1 - \frac{Y_w + Y_e}{2} \right) \cos z + (g_2 x_2 - g_1 x_1 + h - c) \sin z.$$

The following is the process for finding $h - c$. Let t_1 be the noted time of superior transit of a star whose N.P.D. is δ , and t_2 the noted time of inferior transit corrected for the clock's rate and change of the star's R.A. in the interval (12^h) between the transits. Then if ξ' be the value of ξ for the former transit and ξ'' that for the other,

$$(t_2 - \frac{\xi''}{15} \operatorname{cosec} \delta) - (t_1 + \frac{\xi'}{15} \operatorname{cosec} \delta) = 12^h.$$

But on the supposition of cylindrical and equal pivots,

$$(t_2 - \frac{\xi''_1}{15} \operatorname{cosec} \delta) - (t_1 + \frac{\xi'_1}{15} \operatorname{cosec} \delta) = 12^h.$$

$$\text{Hence} \quad \xi'' - \xi''_1 + \xi' - \xi'_1 = 0.$$

Consequently putting for brevity y' or y'' for $f_2 y_2 - f_1 y_1$, and x' or x'' for $g_2 x_2 - g_1 x_1$, according as the transit is above or below the pole, we shall have, l being the colatitude of the Observatory,

$$\xi'' - \xi''_1 = \pm \frac{Y_e - Y_w}{2} + \left(y'' - \frac{Y_w + Y_e}{2} \right) \cos(l + \delta) - (x'' + h - c) \sin(l + \delta),$$

$$\xi' - \xi'_1 = \pm \frac{Y_e - Y_w}{2} + \left(y' - \frac{Y_w + Y_e}{2} \right) \cos(l - \delta) - (x' + h - c) \sin(l - \delta),$$

whence it will be readily found that

$$h - c = \pm \frac{Y_e - Y_w}{2 \sin l \cos \delta} - \frac{Y_w + Y_e}{2} \cot l + \frac{y'' \cos(l + \delta) + y' \cos(l - \delta) - x'' \sin(l + \delta) - x' \sin(l - \delta)}{2 \sin l \cos \delta}.$$

The constants in the expression for $\xi - \xi_1$ being thus found, the correction in time for the form of the pivots is obtained by the formula,

$$\text{Correction} = \frac{\xi - \xi_1}{15} \operatorname{cosec} \text{N.P.D.}$$

In the year 1850 two sets of measures were taken for the determination of this correction, one on June 19, and the other on July 16. The following are the data obtained on the former day for the values of the constants.

The distance between the dots = $49^{\text{in}}.7$. The Telescope pointing to the Nadir, and Illumination West, the diameter of the East circle = $12^{\circ}.477$, and that of the West circle = $12^{\circ}.348$, $Y_2 = 9^{\circ}.898$, and $Y_1 = 9^{\circ}.380$. From these data and the known diameters of the circles in linear measure it was found that $Y_w = +11''.83$. After reversing the instrument the diameter of the East circle was $12^{\circ}.664$, and that of the West circle $12^{\circ}.167$, $Y'_2 = 8^{\circ}.895$, and $Y'_1 = 10^{\circ}.426$. Hence by calculation, $Y_e = -19''.92$.

The micrometer measures for calculating the effect of the forms of the pivots were only taken for the position of Illumination East. The following were the different measures of the diameters of the circles taken in that position of the instrument for the values of the micrometer revolutions.

Horizontal Measures.

Zen. Dist. South.	West Micrometer.	East Micrometer.
+ 90°	12,186	12,694
50	12,215	12,645
0	12,194	12,642
- 39°. 17' } Polaris SP. }	12,252	12,645
- 90	12,227	12,652
Means	12,215	12,656

Vertical Measures.

Zen. Dist. South.	West Micrometer.	East Micrometer.
180°	12,167	12,664
- 50	12,152	12,640
Means	12,160	12,640

As the separate measures differ little from each other, the above means of the horizontal measures are used for all the calculations of horizontal ordinates, and the means of the vertical measures for the vertical ordinates.

The micrometer readings for bisections of the dots were taken for Zenith Distances of 0° , 10° , 20° , &c. North and South. Those for the Zenith Distances of Polaris and Polaris SP, being interpolated to second differences were found to be as follows: for Polaris, $y_2 = 10^r,403$, $y_1 = 10^r,484$, $x_2 = 9^r,802$, $x_1 = 9^r,943$; for Polaris SP, $y_2 = 10^r,285$, $y_1 = 10^r,435$, $x_2 = 9^r,791$, $x_1 = 9^r,940$. From these data and the foregoing mean measures of the diameters of the circles, the following results were obtained:

$$\begin{aligned} y' \cos(l - \delta) &= +2'',05, & x' \sin(l - \delta) &= +0'',54, \\ y'' \cos(l + \delta) &= +1'',12, & x'' \sin(l + \delta) &= +0'',49, \end{aligned}$$

the star's N.P.D. being $1^\circ.29',7$ and the colatitude $37^\circ.47',1$. The polar distance of Polaris was selected because this star was used for finding by the ordinary process the azimuth error.

The above results suffice for the calculation of the constants in the formula for $\xi - \xi_1$. The calculations being gone through, the resulting formula is,

$$\xi - \xi_1 = -15'',88 + (f_2 y_2 - f_1 y_1 + 4'',04) \cos z + (g_2 x_2 - g_1 x_1 - 18'',96) \sin z.$$

It must, however, be remarked that in the investigation of this expression, the collimation and level errors from which ξ_1 is calculated, are supposed to be obtained from the values of a and b given by the collimating eye-piece and by reversing the instrument. But in the reduction of the transit observations the adopted level error is found by the spirit-level, and L_e is used in the place of $\frac{a+b}{2}$ and $L_e - b$ in the place of $\frac{a-b}{2}$; and for Illumination West, L_w is used for $\frac{a+b}{2}$ and $L_w - a$ for $-\frac{a-b}{2}$. Hence putting l for $\frac{a+b}{2}$, we require to know $L_e - l$, or $L_w - l$. Mean values of these quantities were inferred from the following determinations of level error made nearly contemporaneously by the two methods.

Date of Reversion.	a	b	l	L_w	L_e	$L_w - l$	$L_e - l$
1849, Feb. 28 ...	$-4'',06$...	$-5'',54$...	$-4'',80$...	$-6'',06$...	$-4'',12$...	$-1'',26$...	$+0'',68$
Aug. 24 ...	$+3'',29$...	$+2'',39$...	$+2'',84$...	$+0'',78$...	$+2'',98$...	$-2'',06$...	$+0'',14$
1850, April 13 ...	$+2'',54$...	$+3'',14$...	$+2'',84$...	$+0'',53$...	$+3'',08$...	$-2'',31$...	$+0'',24$
May 15 ...	$+1'',67$...	$+1'',61$...	$+1'',64$...	$-0'',23$...	$+2'',05$...	$-1'',87$...	$+0'',41$
June 19 ...	$+1'',76$...	$+0'',51$...	$+1'',14$...	$-1'',21$...	$+1'',26$...	$-2'',35$...	$+0'',12$
July 16 ...	$+0'',67$...	$-0'',65$...	$+0'',01$...	$-1'',21$...	$+0'',56$...	$-1'',22$...	$+0'',55$

The mean values of $L_w - l$ and $L_e - l$ are $-1'',85$ and $+0,36$. Hence in the calculation of ξ_1 , the collimation and level errors have each been increased by $0'',36$, and the consequent increment of azimuth error as found by imaginary transits of Polaris above and below pole being $+1'',06$, the expression for $\xi - \xi_1$ which has been used is the following:

$$\xi - \xi_1 = -16'',24 + (f_2 y_2 - f_1 y_1 + 3'',68) \cos z + (g_2 x_2 - g_1 x_1 - 20'',02) \sin z.$$

Subjoined are the observed values of y_1 , y_2 , x_1 , x_2 for different zenith distances, and the resulting values of $\xi - \xi_1$ given by this formula.

The measures of July 16 were taken for Zenith Distances differing by 5° , but like those of June 19, only apply to the position of the instrument in which the Illumination is East. By exact measurement the distance between the dots was ascertained to be $49^{\text{in}},84$, the caps on which they are engraved not being pushed on the pivots so far as on June 19. The following are the data for obtaining the formula for $\xi - \xi_1$, the letters having the significations already explained.

Illumination West, Diameter of East circle = $12^{\circ},507$, Diameter of West circle = $12^{\circ},393$, $Y_2 = 10^{\circ},215$, $Y_1 = 8^{\circ},861$. Hence $Y_w = +24'',33$.

Illumination East, Diameter of East circle = $12^{\circ},683$, Diameter of West circle = $12^{\circ},185$, $Y'_2 = 9^{\circ},806$, $Y'_1 = 9^{\circ},360$. Hence $Y_e = +11'',36$.

The following were the measures of the Diameters of the circles, Illumination East.

<i>Vertical Measures.</i>				<i>Horizontal Measures.</i>			
Zen. Dist. South.	West Micrometer.	East Micrometer.		Zen. Dist. South.	West Micrometer.	East Micrometer.	
+ 90°	12,168	12,736		+ 90°	12,235	12,672	
+ 45	12,177	12,711		+ 45	12,260	12,653	
0	12,185	12,683		0	12,254	12,639	
- 45	12,198	12,670		- 45	12,263	12,626	
- 90	12,218	12,657		- 90	12,241	12,622	

The micrometer readings for the zenith distance of Polaris, obtained by interpolation, were $y_2 = 10^{\circ},366$, $y_1 = 8^{\circ},627$, $x_2 = 9^{\circ},314$, $x_1 = 10^{\circ},829$, and those for the zenith distance of Polaris SP, $y_2 = 10^{\circ},331$, $y_1 = 8^{\circ},575$, $x_2 = 9^{\circ},301$, $x_1 = 10^{\circ},869$. Hence using the measures of the Diameters of the circles corresponding to -45° of zenith distance, it is found that $y' = +30'',04$, $y'' = +30'',29$, $x' = -21'',09$, $x'' = -21'',90$. By these results the general formula becomes,

$$\xi - \xi_1 = -6'',49 + (f_2 y_2 - f_1 y_1 - 17'',85) \cos z + (g_2 x_2 - g_1 x_1 + 26'',81) \sin z.$$

If the constants be corrected respectively by $-0'',36$, $-0'',36$ and $-1'',06$, for the same reason as on June 19, the resulting equation is,

$$\xi - \xi_1 = -6'',85 + (f_2 y_2 - f_1 y_1 - 18'',21) \cos z + (g_2 x_2 - g_1 x_1 + 25'',75) \sin z.$$

The equation actually employed was obtained in another manner, and differed from this in having $26'',20$ in the place of $25'',75$ in the last term through a mistake in calculation. The micrometer readings, y_1 , y_2 , x_1 , x_2 , and the values of $\xi - \xi_1$ given by the formula which was made use of, are contained in the following Table.

Zen. Dist. South.	y_1	y_2	x_1	x_2	$\xi - \xi_1$	Zen. Dist. South.	y_1	y_2	x_1	x_2	$\xi - \xi_1$

The above micrometer readings are all means of three readings corresponding to a bisection of the dot and to contacts of the wire on opposite sides of it. The values of the micrometer revolutions used for calculating $\xi - \xi_1$ were interpolated from those deduced from the measures of the diameters of the circles given above. The results of the observations of June 19 and July 16 are both taken into account in forming the final values of $\xi - \xi_1$. For zenith distances of 0° , 10° , 20° , &c., these are simply the means between the results of the two days: but for the intermediate zenith distances the adopted values were obtained by making the excess of any value above that of July 16 equal to the mean of the excesses of the preceding and following means above the values of that day. The following is a list of the final values of $\xi - \xi_1$ and of the corresponding corrections of the transit times for the focus of the pivots, the Illumination being East.

Zen. Dist. South.	$\xi - \xi_1$	Correction for forms of pivots.	Zen. Dist. South.	$\xi - \xi_1$	Correction for forms of pivots.	Zen. Dist. South.	$\xi - \xi_1$	Correction for forms of pivots.

From this Table one more convenient for use was formed in which the argument was North Polar Distance, and from which the corrections applied in the reduction of the observations were interpolated. The corrections for Polaris and Polaris SP were $-0^s,29$ and $+0^s,07$; and those for δ Ursæ Minoris and δ Ursæ Minoris SP, $-0^s,35$ and $+0^s,18$.

During the year 1850 the Illumination was West only from Jan. 1 to Jan. 7, from April 5 to April 10, and during part of July 16, and the corrections for forms of the pivots during those intervals were interpolated from the following list, the formation of which will be explained in giving an account of the corrections used in the year 1851.

N.P.D.	Correction.	N.P.D.	Correction.	N.P.D.	Correction.
55	$+0,02$	80	$-0,04$	105	$+0,08$
60	$+0,01$	85	$-0,02$	110	$+0,10$
65	$+0,05$	90	$+0,03$	115	$+0,10$
70	$+0,03$	95	$+0,06$	120	$+0,12$
75	$-0,02$	100	$+0,05$	125	$+0,13$

All the concluded times of transit are corrected for the forms of the pivots previous to the application of the other instrumental errors.

Collimation Error. According to the foregoing investigation of corrections for the forms of the pivots, the collimation error supposed to be used in the reduction of the transits is $\frac{a-b}{2} + 0'',36$ for Illumination East, and the level error that immediately given by the spirit-level. But it being supposed inadvertently that the quantity $+0'',36$ was included in the correction for forms of the pivots, the collimation error of the middle wire D actually used is $\frac{a-b}{2}$, and the level error $L_e - 0'',36$. As this discrepancy was not discovered till the transits were all reduced, and its effect on the reduction to the meridian scarcely differed in any case more than $0^s,01$ from a mean value $0^s,10$ which might be considered to be included in clock error, it was not thought worth while to alter the calculations. Also for the short intervals during which the Illumination was West, the adopted collimation error is that given by the collimating eye-piece. The following were the determinations of collimation error in 1850, all made by the collimating eye-piece.

Jan. 11. $0^h - 1^h$. Measures were taken just before and after reversing the instrument.

Illumination West.

Mean of 6 readings, micrometer-wire coinciding with its image.....	$23,665$
..... 6 with D	$23,936$

Illumination East.

Mean of 6 readings, micrometer-wire coinciding with its image.....	$24,200$
--	----------

The coincidence with D after the reversion, not being taken, is assumed to be the same as before the reversion. Hence by the process explained in p. iv, $a = +4''.62$ and $b = +4''.50$. And as by the Table of Intervals in p. xxix the mean of all the wires was nearer to the Illumination end of the axis than D by $0''.90$, the concluded collimation error, taking into account $-0''.18$ for diurnal aberration, is $-0''.06 + 0''.90 - 0''.18$, or $+0''.66$ before the reversion, and $+0''.06 - 0''.90 - 0''.18$, or $-1''.02$ after the reversion. The value $+0''.7$ is used before Jan. 11, and the value $-1''.0$ after that date.

April 1, 0^h. The collimation error was obtained by the collimating eye-piece and levelling, without reversing the instrument. The image of the micrometer-wire vibrated very much, owing probably to strong wind which prevailed at the time, and the measures were consequently somewhat uncertain.

Illumination East.

Mean of 10 readings, the image of D being mid-way between D and the micrometer-wire	} 24,583
Mean of 6 readings, the micrometer-wire coinciding with D	23,864

In this instance, the reading for coincidence of the micrometer-wire with its image is obtained by adding to the reading for coincidence with D *one-fourth* the difference of the two readings. This method, consequently, tends to diminish the effect of errors in the micrometer readings. The result is $24''.044$, and $\therefore b = +3''.07$. By levelling about the same time, $L_e = +3''.85$; and as the mean excess of L_e above $\frac{a+b}{2}$ has been shewn to be $+0''.36$, it follows that $\frac{a-b}{2} = +0''.42$, which is the error of collimation of D .

Hence the concluded error of collimation is $-0''.66$, which is used from Feb. 23.

April 13, 0^h—1^h. The Transit had been several times reversed to make trial of the micrometer-microscopes used for bisecting the dots at the ends of the pivots, and to test a new counterpoise apparatus, the application of which was required in consequence of the removal of the old lever counterpoises to make room for the microscopes. The new counterpoises are attached to the interior faces of the Piers, and press upwards against the arms of the Transit by means of springs and friction-wheels. After making these arrangements the collimation error was found as follows.

Illumination West.

Mean of 7 readings, the image of D being mid-way between D and the micrometer-wire (M)	} 24,324
Mean of 6 readings, micrometer-wire coinciding with D	23,919

Illumination East.

Mean of 6 readings, the image of D equidistant from D and M	} 24,665
..... 6 M coinciding with D	23,928

Hence the reading for coincidence of the micrometer-wire with its image was $23''.770$ before the reversion, and $24''.112$ after the reversion. Consequently $a = +2''.54$, $b = +3''.14$, and $\frac{a-b}{2} = -0''.30$. Hence the concluded Collimation error, Illumination West, is $+1''.02$, which is used April 5—10, and the concluded Collimation Error, Illumination East, is $-1''.38$, which is used from April 15.

May 14. 23^h. The Transit had been reversed for the same purpose as on April 13. On this occasion two sets of measures were taken, the first exhibiting a continual change of reading for which I could not account. The means, however, of the two sets were

very nearly the same. The measures were not altogether satisfactory, the wind blowing hard at the time, and the reflected image being faint and unsteady. Before the second set, the object-glass, which had dust on it, was wiped, and the image was then better seen.

Illumination West.

Mean of 16 readings, the image of D equidistant from D and M	r. 23,460
..... 6 M coinciding with D	23,852

From these measures, by calculating as before, $a = +1''.67$.

May 15. 11^h. The instrument had been reversed at 0^h, and measures taken with reference to the forms of the pivots. The reflected image being very faint and unsteady, apparently from the effect of the wind, the readings for collimation error were uncertain.

Illumination East.

Mean of 6 readings, the image of D equidistant from D and M	r. 24,234
..... 6 M coinciding with D	23,856

Hence it is found that $b = +1''.61$. Taking this value with that of a above, the concluded collimation error, Illumination West, is $+0''.69$, and the concluded collimation error, Illumination East, is $-1''.05$. The former was not required for use; the latter is used from May 1.

June 19. 2^h. The Transit had been reversed for measures to determine the effect of the forms of the pivots. The reflected image was very faint.

Illumination West.

Mean of 7 readings, the image of D equidistant from D and M	r. 23,572
..... 7 M coinciding with D	23,868

By these measures $a = +1''.26$. The value $+1''.76$ used in calculating $L_w - l$ and $L_e - l$, (see p. xxxii), was obtained by a mistake, and those quantities should consequently be $-1''.80$ and $+0''.40$.

June 19. 10^h. After the reversion, wire D was close to its image, and the micrometer-wire was placed by guess between them.

Illumination East.

Mean of 6 readings, M coinciding with its image	r. 23,903
..... 6 with D	23,873

Hence $b = +0''.51$, and $\frac{a-b}{2} = +0''.37$. The concluded collimation error is therefore $+0''.35$ or $-0''.71$, according as the Illumination is West or East. The latter value is used from June 1.

July 16. 0^h. 1^h. The determination of collimation error on this day had reference to the calculation of the effect of the forms of the pivots. For the sake of experiment the trough of mercury was removed to a greater distance from the object-glass, but the reflected image was not thereby improved, and was somewhat fainter. The readings for coincidence of the micrometer-wire with its image were difficult and uncertain on account of the closeness of the wire D .

Illumination West.

Mean of 7 readings, M coinciding with its image	r. 23,839
..... 6 with D	23,878

Illumination East.

Mean of 6 readings, M coinciding with its image	r. 23,835
..... 6 with D	23,873

Hence $a = +0''.67$, $b = -0''.65$, and $\frac{a-b}{2} = +0''.66$.

July 17. 22^h. On account of the uncertainty of the foregoing readings, arising from the position of *D*, the wire-frame was shifted and the following readings were then taken.

Illumination East.

Mean of 6 readings, <i>D</i> equidistant from its image and <i>M</i>	^{r.} 23,418
..... 6 <i>M</i> coinciding with <i>D</i>	23,697

Illumination West.

Mean of 7 readings, <i>D</i> equidistant from its image and <i>M</i>	^{r.} 23,324
..... 6 <i>M</i> coinciding with <i>D</i>	23,702

Illumination East.

Mean of 7 readings, <i>D</i> equidistant from its image and <i>M</i>	^{r.} 23,393
..... 6 <i>M</i> coinciding with <i>D</i>	23,690

In these cases the interval between *D* and the vertical plane through the optical centre of the object-glass is *half* the interval between *D* and *M*. This arrangement of the wires and their images is therefore not so good as that made on April 1. As the micrometer readings increase as the wire moves from the Illumination, it will be seen that from the first and second measures $a = -3'',22$, $b = +2'',39$ and $\frac{a-b}{2} = -2'',80$; and from the second and third measures $a = -3'',22$, $b = +2'',52$, and $\frac{a-b}{2} = -2'',87$. It appears by the coincidences with *D* taken July 16 and 17, that the wire-frame was shifted through $+3'',00$. Hence the two foregoing values of $\frac{a-b}{2}$ corrected for this quantity are $+0'',20$ and $+0'',13$. Taking these with the value obtained on July 16, the mean of the three is $+0'',33$. Hence the concluded collimation error before the shifting of the wire-frame is $+0'',39$ or $-0'',75$, according as the Illumination is West or East. The former value is used for the observation of the Sun July 16, and the latter for the other observations of that day and those of July 17.

Shortly after the measures of July 17 the wire-frame was again shifted in order that the collimation error might not remain large, and by coincidences with *D* before and after, the amount of shifting was found to be $-2'',59$. Hence the collimation error was altered to $-3'',00 + 2'',59 - 0'',75$, or $-1'',16$, which is the value used from July 21.

While taking the third set of measures on July 17, I remarked that the reading for coincidence of the micrometer-wire with its image varied on moving the Telescope northward or southward from the Zenith, in consequence of the wire not being accurately parallel to the plane of the meridian. To obviate this source of error the measures in future are taken in that position of the Telescope in which the horizontal wires between which the transits are observed are reciprocally coincident with their images. It is feared that inattention to this adjustment may have affected previous results.

Dec. 6. 0 $\frac{1}{2}$ ^h. Determination of the collimation error by the collimating eye-piece, without reversing the instrument.

Illumination East.

Mean of 6 readings, <i>D</i> equidistant from its image and <i>M</i>	^{r.} 23,509
..... 6 <i>M</i> coinciding with <i>D</i>	23,830

Hence the reading for coincidence of *M* with its image is 23,990, and $b = +2'',73$. By levelling Dec. 6, 1^h, $L_e - 0'',36 = +2'',73$. Hence $L_e - 0'',36 - b = 0'',00$, and the concluded error of collimation, Illumination East, is $-1'',08$. This value is used from Sept. 30 to the end of the year. The result seems to shew that the collimation error was steady in the interval between this determination and that of July 17.

Level Errors in 1850.

* * In the reduction of the observations the values of level error are taken to the nearest tenth of a second.

It has already been stated that the adopted level errors, Illumination East, are those given by the spirit-level diminished by the quantity 0'',36, which strictly should not have been applied. For the observations of April 5—10 and the observation of the Sun on July 16, during which the Illumination was West, the level errors are those given immediately by the spirit-level. Previous to Jan. 25, the level error could not be obtained by the spirit-level on account of the lengthening of the bubble by the depression of temperature. The adopted level error for the observations on Jan. 1—7 is the mean between the values of a and b given by the measures taken with the collimating eye-piece on Jan. 11. It would have been more correct to use $\frac{a+b}{2} + 1'',85$, this value agreeing more nearly with what would be given

by the spirit-level (see p. xxxii). But as there are no determinations of azimuth error depending on the adopted level error, the apparent R.A. would be very little changed by using the more correct value.

In all the levellings the Telescope was horizontal and pointed southward, with the exception of the second on July 15, which was taken with the Telescope horizontal and looking northward, and is not made use of. The first levelling of April 13 and the first of May 15, the former taken soon after fixing the spring-counterpoises, and the latter for trial of the pier-microscopes, were not required for use. Also the first levelling of Jan. 25, during which the bubble was rapidly changing, is not used.

The measure of the inequality of the radii of the pivots, obtained in the manner explained in Vol. X. p. xxviii, is 0'',57 as given by the levellings of April 1 and April 8, and 0'',59, 0'',53, 0'',57, and 0'',41, as given respectively by the levellings of April 13, May 15, June 19, and July 15—16. These shew an increase upon the quantities obtained in 1849. (See p. vii.)

The assumed Mean R.A. were deduced from the results of the observations of the fundamental stars in 1849 in the manner explained in p. xii. The mean excess above the R.A. of the Nautical Almanac, excluding Polaris and δ Ursæ Minoris, is + 0,089 as in 1849.

In the transits of 1850 there are only two instances (excluding Polaris) in which observations by different observers occur in the same group, those on April 28 and September 12. In the former the transit of B, which appeared to indicate personal equation, is not made use of; and in the latter, B's clock-errors, contrary to former experience, agreed very nearly with T's, and have accordingly been grouped with them.

It is the practice to record transits taken at fewer than three wires, and to reduce them as other observations. But in general these observations are eventually rejected, especially if they refer to fundamental stars. In the printed transits of 1850 there are, however, several exceptions to this rule. The observations of γ Aquilæ January 5, β Lyræ February 3, and Ophiuchi August 20, and of the Moon November 12, were retained through inadvertence. Those of α Andromedæ February 19, β Aquilæ July 11, Procyon Aug. 6, and α Pegasi Oct. 17, were used for clock-error because there were few other clock stars in the same groups: but in such cases, as mentioned in the notes, the weight given to each clock-error is nearly proportional to the number of wires on which it depends. The transits of Polaris at one wire on November 4 and 5 are used with that of November 6 at three wires, to obtain an azimuth error of greater weight, but are not reduced to Apparent R.A. There are also observations of moving bodies at fewer than three wires, which are taken notice of in the remarks to the collection of observations of the Sun, Moon, and Planets in pp. 280—286.

II. *Mean Right Ascensions of the Fundamental Stars, as deduced from the separate observations.* Pages 206—209.

The results of the separate transits of the Fundamental Stars are arranged by themselves, because each star is generally observed a large number of times in the course of the year; but the separate results of the observations of the other stars, together with the mean results of the year's observations of all the stars, are collected in the next section. This arrangement, which differs from that of former years, has been adopted for the sake of saving space.

III. *Mean Right Ascensions of Stars deduced from the separate observations, and Concluded Mean Right Ascensions of the Stars observed in 1850, with the Annual Variations.*
Pages 212—225.

Under this head are collected the days of observation of the stars that are not fundamental, the corrections from the apparent R.A. to the mean R.A., and the resulting mean R.A.; together with the names, approximate N.P.D., number of observations, concluded R.A., and Annual Variations of all the stars observed in the year 1850. The column of 'observed magnitudes' contains only the magnitudes noted at the time of taking the transits.

The corrections from the apparent to the mean R.A., and the Annual Variations, were calculated by the formulæ used for 1849. (See p. xv and p. xxii.)

IV. *Apparent North Polar Distances observed with the Mural Circle.* Pages 228—259.

The arrangement of the printed observations of N.P.D. are the same for 1850 as for the preceding year, with the exception that the times by the clock Molyneux of bisection of the circumpolar stars Polaris, δ Ursæ Minoris, and 51 (Hev.) Cephei are inserted in the space at the bottom of the page, together with the error of the clock as determined by circle transits of known stars, or the difference between Hardy and Molyneux.

For an explanation of the rules according to which the corrections for Runs were in general adopted in the calculation of Zenith Points and in the reduction of the observations see p. xvii. The correction $+10''.1$ used from the beginning of the year was obtained on Dec. 31, 1849. The mean of the values obtained on February 18 and 19 is adopted from Feb. 15. The correction used for the Sun on July 8 is the mean of those of July 6 and July 7.

On July 8 at 4^h, the wires of microscope E were accidentally broken in an attempt to adjust the eye-piece. I immediately put in new wires, thicker than the former and better for bisecting with. In replacing the microscope, the eye-piece accidentally fell and the field-glass was cracked. The use of the microscope was not, however, interfered with, the part of the field required for bisections being unaffected by the fracture. Before replacing the microscope I took out and cleaned the object-glass. It will be seen by the foregoing Table that the Run of the micrometer was increased in consequence of these alterations.

The mean of the three corrections obtained on October 28 and November 1 is used from October 21. The value $+4''.5$ applied to four microscopes on November 2 was deduced from the Runs taken on November 6. The correction used for the observations of Nov. 11—14 is the mean of the three values obtained Nov. 11 and 12.

July 6, 6¹/₂^h, I took the following measures for determining the value of one revolution of the Circle micrometer. The mark on the tower of Grantchester Church, described in p. xxviii of Vol. XVII was made use of. It waved considerably, and was somewhat obscure, the sky being densely clouded and rain falling during a part of the time. Temperature, 59°.5.

The correction for Runs for 5', obtained immediately after the above measures, was $+5''.0$. The mean of the nine differences in the last column, being divided by 24, gives $20''.824$ for the value of the micrometer revolution, which is less than the values obtained in former years. It is, however, to be remarked that before the above measures were taken, the distance of the micrometer-wire from the object-glass had been adjusted so that the wire and its image could be seen with equal distinctness when looked at with the collimating eye-piece. This had not been the case before. It is probable that the wire had been placed so that it could be seen distinctly with the mark on Grantchester tower. I find by calculation that the difference of focal distance for stars and for the mark is one-seventeenth of an inch: consequently after the above adjustment, the micrometer-wire and the mark could not be seen well in focus at the same time. On this account I obtained the value of the micrometer revolution by means of the collimating eye-piece, by placing the wire and its image in coincidence first on one side of the field and then on the other, and reading off the micrometer and the circle in the two positions. The field of the collimating eye-piece is scarcely large enough for this purpose, and when the wire was placed near the border, both it and its image were seen indistinctly. The measures were taken July 7, 22^h, partly by coincidence of the wire and its image, and partly by placing the wire on one side and the other of the image at distances judged to be equal.

Micro- meter reading.	Pointer reading.	Microscope A	B	C	D	E	F	Correction for Runs.	Concluded Circle reading.	Difference.
2,258	246.20	2.37,9	34,4	37,9	36,3	36,5	33,3	+ 0,8	246.22.36,18	' "
20,384	246.25	3.56,2	52,0	58,0	55,5	55,1	51,0	+ 1,2	246.28.54,83	6.18,65
2,281	246.20	2.38,2	35,4	39,7	37,6	38,0	33,5	+ 0,8	246.22.37,20	6.17,63

The corrections for Runs were derived from the Runs taken on July 8. The above micrometer-readings are respectively the means of 11, 10 and 12 separate readings. The value of the micrometer revolution given by the first difference is 20",890, and that given by the other is 20",860. As it was discovered that the circle was not clamped during the first set of measures, some doubt was thrown upon the first value, and the other was consequently adopted for the observations taken subsequently to July 3. The value used previous to that date is 20",850, this being the mean of several preceding determinations. Also the shifting of the wire-frame towards the object-glass would increase the value of the micrometer revolution by about 0",10.

With respect to corrections to the meridian for change of N.P.D. in the interval between the bisection and the transit across the middle wire, it is only necessary to add to what is stated in p. xviii, that for the Sun and Moon the horary variations of N.P.D. are taken from the Nautical Almanac, and that the interval for the Moon is accurately calculated by means of the formula in p. xxix.

* 'Very steady.' This note is omitted in p. 231.

The Zenith Point used from the beginning of the year till the Circle was taken from the wall on Jan. 7 is that obtained Dec. 31, 1849. Between Jan. 7 and Jan. 15 the micrometer apparatus was removed from the Telescope Tube to oil the screw and adjust the comb. On Jan. 17 the micrometer-wire was adjusted equatorially. Between June 22 and July 5, the microscopes were re-adjusted, and the micrometer-wire was adjusted equatorially and as to its distance from the object-glass. The Zenith Point used on July 4 was inferred from the reflection and direct observations of δ Ursæ Minoris on that day, because the equatorial adjustment of the micrometer-wire was effected after the day's observations. The Zenith Point was taken on July 8 on account of the accident to the wires of Microscope E already mentioned. The Zenith Point used on Nov. 2 is that of Nov. 6 as given by the four microscopes which were read off for the observations of the former day. The tendency of the zenith point to a maximum at the hottest part of the year is observable in this list as in that for 1849.

The corrections for deducing the Mean from the Apparent N.P.D., and the Annual Variations, in pages 262—276, were calculated by the formulæ used for 1849. (See pages xxi and xxii.)

Mean Excess for each Star of the adopted Zenith Points above the Zenith Points given by direct and reflection observations in the year 1850.

+ 35	+ 0.98	— 0.24	+ 80	+ 0.64	+ 0.10			

The correction of the assumed co-latitude is $+0''.37$. According to the above Table the Zenith direction as given by the collimating eye-piece is $+0''.72$ more *southward* than the direction given by direct and reflection observations of Stars. In 1849 the deviation was *northward*. (See the Errata.)

V. *Horizontal and Vertical Measures of the Diameters of the Sun and Moon, compared with Tabular Diameters.* Pages 278 and 279.

The sidereal intervals occupied by transits of diameters are the differences of the concluded transits of the first and second Limbs over the mean of the seven wires, extracted from column 10 of the observed R.A.; and the vertical diameters by observation are the differences of the apparent N.P.D. of the North and South Limbs, extracted from the Circle observations, and corrected for the difference of the Parallaxes of the Limbs. In the case of the Moon a correction is applied for defect of illumination of one of the Limbs. The formulæ for calculating the Moon's Parallax and the corrections for the defect of illumination will be given hereafter.

The tabular intervals occupied by the transits of diameters, and the tabular diameters for the Sun, and, in the first instance, for the Moon, were taken from the Nautical Almanac, the Moon's semi-diameter being interpolated to second differences. But as Adams's corrections were subsequently applied to the Moon's Parallaxes, the tabular semi-diameter was taken equal to the corrected Horizontal Equatorial Parallax multiplied by the constant 0.273114. (See Naut. Alm. of 1857, p. vii.) The tabular interval of transit of the Moon's diameter was then altered in the ratio of the new value of the semi-diameter to the interpolated value.

The differences between the observed and the tabular values of the intervals of transit and of the vertical diameters are exhibited for the purpose of furnishing data for correcting the tabular diameters. In the case of the Moon the tabular error of the interval of transit is converted into error of diameter in arc, by assuming the latter to have to the Moon's semi-diameter the same ratio that the former has to the sidereal interval occupied by the transit of the semi-diameter.

VI. *Right Ascensions and North Polar Distances of the Sun, the Moon, and Planets observed in 1850, compared with Tabular R.A. and N.P.D.; with the Greenwich Mean Solar Times of Transit of centre.* Pages 280—286.

The concluded Right Ascensions and North Polar Distances of the centres of the moving bodies are deduced from their apparent R.A. and N.P.D. in the previous part of the work, by applying corrections of which the explanation is as follows.

The corrections applied to Apparent Right Ascensions are those for reducing observations of limbs to observations of centres. It is to be understood that both limbs were observed unless one is mentioned under the head of 'Limb observed,' and that the concluded R.A. of centre is the mean of the apparent R.A. of the limbs.

When one limb of the Sun is observed, the R.A. of centre is inferred from the apparent R.A. of the Limb, by applying the sidereal time occupied by the transit of the semi-diameter as given in the Nautical Almanac.

The Right Ascension of the Moon at the time of transit of centre is obtained from the observed R.A. of the Limb, by applying the sidereal time occupied by the transit of the semi-diameter, taken, first, from the section of Moon-culminating stars in the Nautical Almanac, and then altered in the ratio of the semi-diameter deduced from Adams's corrected parallax to the interpolated semi-diameter.

The corrections for defect of illumination of one of the Moon's Limbs on April 25 and August 21, the amounts of which are stated at the bottom of page 282, were found by first ascertaining the Moon's distance in R.A. from the point of opposition to the Sun,

and multiplying this distance by the cosine of the Sun's declination. The versed sine of the resulting arc on the Moon's surface, converted into time, is the required correction, and is additive or subtractive according as the second or first limb was defective.

The R.A. of centre for all the other bodies, is that immediately given by observation.

The *Geocentric North Polar Distance of Centre* from observation, is deduced from the observed apparent N.P.D., by applying corrections for parallax, for semi-diameter when a single Limb is observed, and for the error of assumed co-latitude and the discordance of zenith points. In the case of the Sun, the observed apparent N.P.D. of centre is the mean of the observed N.P.D. of the Limbs, and in the case of the Moon the observed apparent N.P.D. of the Limb is the mean of the determinations at the several wires, corrected for the position of the Circle, as will be shortly explained.

The parallaxes of the Sun and Planets were calculated by the formula given in p. xxvii. When both limbs of the Sun are observed, the parallax of each is calculated, for the purpose of correcting the measure of the diameter to what it would be as seen from the Earth's centre, and the mean of the two parallaxes is applied to the apparent N.P.D. of centre.

The formula used for computing the parallax of the Moon's Limbs is

$$\sin p = \frac{r}{r'} \sin (P + \alpha) \sin z,$$

where P is Adams's equatorial horizontal parallax, and the quantity α is a small correction introduced by finding exactly the parallax of the Limb, that is, the angle made by a tangent to the highest or lowest point of the Moon's surface, as seen from the place of observation, with a tangent to the highest or lowest point, as seen from the Earth's centre. In using the above formula, the sine is not considered equal to the arc. The other elements of the calculation are the same as for the planets.

For the calculation of α , which is dependent on the zenith distance, I must refer to the *Cambridge Observations*, Vol. IV, for 1831, p. 147. The following is a table of its values, for the North and South Limbs, and for different zenith distances.

Zenith Distance.	30°	35°	40°	45°	50°	55°	60°	65°	70°	75°	80°
Corr. for N.L.	- 0,03	- 0,04	- 0,05	- 0,06	- 0,06	- 0,07	- 0,08	- 0,08	- 0,09	- 0,09	- 0,09
Corr. for S.L.	+ 0,10	+ 0,11	+ 0,12	+ 0,12	+ 0,13	+ 0,14	+ 0,15	+ 0,15	+ 0,16	+ 0,16	+ 0,16

When a single Limb of the *Sun* is observed with the Circle, the assumed semi-diameter applied to the Geocentric N.P.D. of the Limb, is taken immediately from the Nautical Almanac.

For the *Moon*, the assumed semi-diameter is the equatorial horizontal parallax multiplied by the constant 0,273114.

The corrections applied for defect of illumination of the Moon's North or South Limb, the amounts of which are stated in the notes in pages 282 and 283, were calculated as follows. From the spherical triangle SPM , the angles of which are at P the pole of the heavens, S the Sun's centre, and M the Moon's centre, the angle PMS was calculated from the known parts, PS , PM , and the angle SPM . According as the angle PMS is greater or less than 90° , the North Limb or the South Limb is defective. This calculation was performed whenever both Limbs were observed, to decide which was the defective Limb, and when a single Limb was observed, if it were doubtful whether or not it was defective. The side SM being calculated from the same triangle, and θ being the difference between 90° and the angle PMS , an angle θ' was calculated by

the formula $\sin \theta' = \sin \theta \sin SM$. Then Δ being the measure of the Moon's diameter by the observation, the required correction is $\Delta \tan^2 \frac{\theta'}{2}$, additive or subtractive, according as the South or North Limb was defective.

As the corrections for change of the Moon's N.P.D. reduced the observations to the position of the middle wire, additional small corrections were required on account of the deviation of the middle wire from the meridian. These corrections were calculated as follows.

The collimation, level, and azimuth errors of the middle were first calculated from the following Circle transits.

Date.	Star.	Wire 1.			II.		III.		IV.		V.		Concluded transit over wire III.				
		<i>h.</i>	<i>m.</i>	<i>s.</i>	<i>m.</i>	<i>s.</i>	<i>m.</i>	<i>s.</i>	<i>m.</i>	<i>s.</i>	<i>m.</i>	<i>s.</i>	<i>h.</i>	<i>m.</i>	<i>s.</i>		
July 1 ...	δ Ursæ Minoris R ...	18.	11.	59,5	...	16.	37,0	...	21.	12,0	18.	21.	13,56	
1 ...	δ Ursæ Minoris D ...	18.			25.	49,5	...	30.	28,3	...	18.	21.	12,81
1 ...	β Lyrae	18.	43.	40,3	...	44.	0,1	...	44.	19,5	...	44.	58,9	...	18.	44.	19,62
1 ...	α ² Capricorni.....	20.	8.	56,6	...	9.	13,5	...	9.	30,2	...	9.	47,2	...	20.	9.	30,32
8 ...	δ Ursæ Minoris	18.	11.	17,6	...	15.	55,0	...	20.	32,0	...	25.	10,5	...	29.	46,2	...

The transit of δ Ursæ Minoris July 8 was merely used for finding the intervals of wires I, II, IV and V from wire III, which are assumed to be the same as on July 1. By these intervals, which showed that wire III coincided almost exactly with the mean of the wires, the transits are reduced to wire III. The excess of the reflection transit of July 1 above the direct transit being $+0^s,75$, the level error calculated by the formula in p. xxv is found to be $+0'',40$. By comparisons of Hardy and Molyneux on July 1 and 3 by the intervention of the Solar Chronometer W, M was ascertained to be $16^s,94$ slow at $18^h.50^m$ sidereal time on July 1, and its losing rate to be $0^s,22$ per day. Hence the collimation and azimuth errors being a and c , and the assumed apparent R.A. of the stars July 1, as deduced from the Nautical Almanac, being respectively, $18^h.21^m.2^s,04$, $18^h.44^m.34^s,73$, and $20^h.9^m.45^s,70$, the observations give the following equations for determining a and c :

$$\begin{array}{lll} \delta \text{ Ursæ Minoris R.} & \beta \text{ Lyrae.} & \alpha^2 \text{ Capricorni.} \\ -28,83 = +1,124a - 0,635c. & -1,86 = +0,080a + 0,026c. & -1,58 = +0,068a + 0,062c. \end{array}$$

The mean of the last two equations combined with the first gives $a = -24'',48$ and $c = +2'',07$. From these values of the three errors the following results were obtained by the Transit-reducer mentioned in p. xii.

N.P.D.	Interval from meridian to middle wire.	N.P.D.	Interval from meridian to middle wire.
60°	$+1,8$	95°	$+1,5$
65	$+1,7$	100	$+1,5$
70	$+1,6$	105	$+1,6$
75	$+1,6$	110	$+1,6$
80	$+1,5$	115	$+1,7$
85	$+1,5$	120	$+1,8$
90	$+1,5$		

These results are used for the observations previous to July 3 when the Circle was taken from the wall.

Subsequently to July 3 the position of the Circle was ascertained by Circle transits of various known stars, which gave the following results, the errors of Molyneux being obtained by comparisons with Hardy.

Day of Observation 1850.	Star.	N.P.D.	Interval from meridian to middle wire.	Day of Observation 1850.	Star.	N.P.D.	Interval from meridian to middle wire.
Sept. 28 ...	α^2 Capricorni ...	$103^\circ. 0'$	$-0,90$	Nov. 14 ...	β Aquarii ...	$96^\circ. 14'$	$-1,34$
28 ...	α Aquarii	$91^\circ. 3'$	$-1,15$	14 ...	ϕ Aquarii ...	$96^\circ. 51'$	$-1,75$
28 ...	α Pegasi	$75^\circ. 36'$	$-1,87$	14 ...	ψ^3 Aquarii ...	$100^\circ. 26'$	$-1,46$
28 ...	α Andromedæ ...	$61^\circ. 44'$	$-1,67$	14 ...	27 Piscium ...	$94^\circ. 23'$	$-1,50$
28 ...	β Ceti	$108^\circ. 49'$	$-0,80$	25 ...	Aldebaran ...	$73^\circ. 48'$	$-1,83$

From the above the following mean results, which are used for the latter half of the year, were obtained by graphical construction.

N.P.D.	Interval from meridian to middle wire.	N.P.D.	Interval from meridian to middle wire.
60	-1,85	95	-1,82
65	-1,82	100	-1,22
70	-1,75	105	-1,10
75	-1,72	110	-0,90
80	-1,61	115	-0,83
85	-1,54	120	-0,72
90	-1,43		

The interval from the meridian for any observation being obtained from the foregoing data by interpolation, the change of the Moon's N.P.D. in the interval was calculated from the variation for 10^m in the hourly Ephemeris of the Nautical Almanac.

In addition to the foregoing Circle transits, the following unaccompanied by comparisons of Molyneux with Hardy, were used for finding the approximate error of Molyneux, and reducing observations of Polaris and δ Ursæ Minoris to the meridian. The preceding results shew that the position of the circle was sufficiently exact for this purpose.

* Molyneux had been put forward 4^m. † The apparent R.A. was deduced from the mean R.A. 1849,0 in p. 109.

All the observations of N.P.D. of the Sun, Moon, and Planets have been corrected for the discordance of Zenith Points and the error of the assumed co-latitude by the Table in p. xlvii.

The *Greenwich Mean Solar Time* of transit of centre is calculated from the R.A. of centre at meridian transit in the manner explained in p. xxvii.

In those instances where Circle observations of the Sun and Moon are not accompanied by Transit observations, the Greenwich Mean Solar Time is calculated from the R.A. of centre at Cambridge meridian transit, as deduced from the Nautical Almanac, and corrected in the case of the Moon for approximate tabular error of R.A.

The Greenwich Mean Time for Flora on Oct. 21 was obtained by extending the daily Ephemeris in p. 627 of the Nautical Almanac for 1853, the third differences being supposed constant, and applying a correction for error of the Ephemeris. For the same Planet on Nov. 23 the Greenwich Mean Time was deduced from a contemporaneous Greenwich meridian observation, and that for Hygeia on July 27 from an equatorial observation taken at Berlin on the same day (*Ast. Nach.* Vol. XXXI. p. 377). For Victoria Nov. 23, and for Neptune Aug. 9, Oct. 31, Nov. 25 and Dec. 17, the Greenwich Mean Times were calculated from the R.A. of the respective Ephemerides, and for Egeria on Nov. 28 the Greenwich Mean Time is interpolated from those of Nov. 23, 25 and 29.

The *seconds of Tabular R.A. and N.P.D.*, from which the *Errors of the Tables* are deduced, have been derived for the Sun from the R.A. and N.P.D. at meridian transit in the Nautical Almanac, by applying corrections for the difference of meridians. The seconds of Tabular R.A. of the Moon's centre are calculated, by first applying to the R.A. of the Limb in the section of Moon-culminating stars in the Nautical Almanac, the sidereal time occupied by the transit of the semi-diameter as there given, and then correcting for the difference of meridians. The seconds of N.P.D. of centre are derived from the same section of the Nautical Almanac by merely correcting for the difference of meridians.

The reduction of the Tabular R.A. and N.P.D. of the Sun, Moon, and Planets, from the Greenwich to the Cambridge transit, is facilitated by the use of Table VI. at the end of this Introduction, which gives the means of readily calculating the value of $\frac{22,75}{3600} \times$ the horary variation of Right Ascension or Declination, for all values of the horary variation to 1300 seconds of time or space.

The tabular R.A., N.P.D., and Log. distance of Flora were calculated for the respective Greenwich Mean Times, corrected for aberration, from the following Elements of Dr Brünnow, contained in the *Berliner Jahrbuch* for 1852, p. 382:

Mean Anomaly 1850, Oct. 1,0 Berlin Mean Time	339 . 0 . 6,3	} Mean $\mathcal{A}eq^x$. 1850, Oct. 1, 0.
Longitude of Perihelion	32 . 48 . 27,4	
Longitude of Ascending Node.....	110 . 20 . 13,2	
Angle of Eccentricity.....	9 . 2 . 13,7	
Inclination	5 . 53 . 2,8	
Logarithm of Mean Distance	0,3426964	
Daily increment of Mean Anomaly	1086'',33020	

For the observations included within September 14 and October 15 advantage was taken of the Meridian Ephemeris in the Nautical Almanac for 1853, p. 627, which was calculated from the same Elements. But as by our calculations the R.A. for the meridian transit of Sept. 14 was less by 0^s,07. and the N.P.D. greater by 1'',10, and for the meridian transit of Oct. 12 the R.A. was less by 0^s,10, and N.P.D. greater by 1'',21, than those of the Nautical Almanac, these differences are distributed over the Meridian Ephemeris in order to make it consistent with the results of our calculation. The Log. distance for the observations from Sept. 14 to Oct. 12 were interpolated from the Ephemeris in the *Berliner Jahrbuch* for 1852, p. 393. For correcting the Greenwich Mean Times for aberration, the approximate Ephemeris in p. 626 of the Nautical Almanac was made use of.

The tabular R.A., N.P.D., and Log. distance of Victoria were interpolated from the Ephemeris of M. Yvon Villarceau in the *Astronomische Nachrichten*, Vol. XXXI. No. 741.

The tabular R.A. and N.P.D. of Iris to June 1 were taken from the Meridian Ephemeris in the Nautical Almanac for 1853, p. 629, (corrected as mentioned below), and Log. distance from p. 391 of the *Berliner Jahrbuch* for 1852. For the observations subsequent to June 1 the tabular places and Log. distance were calculated from Schubert's Elements in p. 382 of the *Berliner Jahrbuch*, which are the Elements used in the calculations of the Nautical Almanac, viz :

Mean Anomaly 1850, May 16,0 Berlin Mean Time	202 . 34 . 28,5	} Mean $\mathcal{A}eq^x$. 1850, May 16, 0.
Longitude of Perihelion	41 . 24 . 10,9	
Longitude of Ascending Node	259 . 42 . 50,1	
Angle of Eccentricity	13 . 25 . 49,2	
Inclination	5 . 28 . 16,6	
Logarithm of Mean Distance	0,3774912	
Daily increment of Mean Anomaly	963'',31818	

As our calculated places for the meridian transits of May 2 and June 1, compared with those of the Nautical Almanac gave the excesses $-0^s,007$ and $-0^s,018$ of R.A., and the excesses $+0'',08$ and $-0'',12$ of N.P.D., these corrections for the sake of uniformity have been distributed over the tabular places anterior to June 3. The rates of change of R.A. and N.P.D. from which the aberration corrections of June 3, 4, 7, and 8 were calculated, were deduced from a combination of Cambridge and Greenwich observations.

The tabular places and Log. distance of Hebe were calculated for the respective Greenwich Mean Times, corrected for aberration, from Luther's Elements in p. 382 of the *Berliner Jahrbuch* for 1852, viz.:

Mean Anomaly 1850, April 1,0 Berlin Mean Time...	174 . 35 . 31,0	} Mean $\mathcal{A}eq^x$. 1850, April 1, 0.
Longitude of Perihelion.....	15 . 10 . 7,1	
Longitude of Ascending Node	138 . 31 . 38,2	
Angle of Eccentricity	11 . 36 . 18,6	
Inclination.....	14 . 46 . 42,4	
Logarithm of Mean Distance	0,3849569	
Daily increment of Mean Anomaly	938",79562	

The corrections of the Greenwich Mean Times for aberration were deduced from the approximate Ephemeris in p. 388 of the same work. The tabular place of March 28 is taken from the Meridian Ephemeris in p. 633 of the Nautical Almanac for 1853, the R.A. corrected by $-0^s,06$ and the N.P.D. by $+0'',03$, these corrections being inferred from the differences between our computed places for the meridian transits of March 27 and April 10 and those of the Nautical Almanac. The Log. distance for March 28 was taken from the Berlin daily Ephemeris.

The tabular places and Log. distance of Parthenope were interpolated from Luther's Ephemeris in the *Astronomische Nachrichten*, Vol. XXX. No. 720, and those of Hygeia from D'Arrest's Ephemeris in the Monthly Notices of the Royal Astronomical Society, Vol. X. p. 130. The place of the latter Planet for August 14 was calculated from D'Arrest's Elements, the Ephemeris extending only to July 31; and as by comparison with a place which we calculated for July 31, the R.A. of the Ephemeris was in excess by $+3^s,85$ and its N.P.D. by $-1'',16$, these corrections have been applied to the computed place of August 14. It must however be remarked that the resulting tabular errors are uncertain.

The tabular places and the parallaxes of Egeria were inferred from the comparison made by Professor Hubbard of the Washington Observatory, in the *Astronomical Journal* (Vol. II. p. 66), of places computed from his second Elements, with the Cambridge observations as published in the Monthly Notices of the Royal Astronomical Society, Vol. XI. p. 33. The R.A. and N.P.D. there given differ slightly from the finally reduced values in p. 285.

The tabular places of Neptune were interpolated from Walker's Ephemeris in the *Astronomische Nachrichten*, Vol. XXXI. No. 721, and the parallaxes were inferred from the values of Log. distance added to the Ephemeris.

The tabular R.A., N.P.D., and Log. distance of Petersen's Third Comet were calculated for the respective Greenwich Mean Times, corrected for aberration, from the following Elements of M. Yvon Villarceau in the *Astronomische Nachrichten*, Vol. XXXI. No. 735.

Perihelion Passage, 1850, July 23, 52671 Paris M.T.

Longitude of the Perihelion	273 . 24 . 31,6	} Mean $\mathcal{A}eq^x$. of 1850, July 23, 5.
Longitude of the Ascending Node	92 . 53 . 28,9	
Inclination	68 . 12 . 4,6	
Perihelion Distance	1,0815025	
Motion direct.		

The corrections of the Greenwich Mean Times for aberration were deduced from the Ephemeris of Mr Sonntag in the *Astronomische Nachrichten*, Vol. XXX. No. 720.

The *Determination of the Position of the Ecliptic and of the mean error of the assumed Right Ascensions of the Fundamental Stars from the Transit and Circle Observations of the Sun* in 1850, in pages 287 and 288, has been inserted to give the means of inferring absolute errors of the Solar, Lunar, and Planetary Tables from the observations of this Volume. The calculations have been made on the following principles.

The true longitude λ , and true North Polar Distance Δ , of the Sun's centre, and the true obliquity I , at any instant, are related to each other by the equation,

$$\cos \Delta = \sin \lambda \sin I,$$

and the tabular longitude $\lambda + \delta\lambda$, the tabular North Polar Distance $\Delta + \delta\Delta$, and the assumed obliquity $I + \delta I$, in the Nautical Almanac, for the same instant, by the equation,

$$\cos(\Delta + \delta\Delta) = \sin(\lambda + \delta\lambda) \sin(I + \delta I).$$

Hence neglecting powers of the errors $\delta\lambda$, $\delta\Delta$, δI , above the first,

$$\Delta\delta + \operatorname{cosec} \Delta \cos \lambda \sin I \delta\lambda + \operatorname{cosec} \Delta \sin \lambda \cos I \delta I = 0 \dots\dots\dots (A).$$

Now it is assumed that the changes of λ and I in the course of a year are in accordance with the theoretical calculations, and consequently that their values, as given in the Nautical Almanac, are affected, if by any, by constant errors, which it is proposed to find.

The actual errors of the Solar Tables in N.P.D. cannot be immediately derived from the errors in the columns of pages 280—282, because though mere errors of observation may be supposed eliminated in the mean result from a large number of observations, there may still remain uncorrected instrumental errors and errors of reduction. Representing therefore by a any error in N.P.D. taken from those columns, and by p the excess of the observed above the true N.P.D. we shall have,

$$\delta\Delta = (\text{Tabular N.P.D.} - \text{observed N.P.D.}) + (\text{observed N.P.D.} - \text{true N.P.D.}) = a + p;$$

and as we are ignorant of the causes to which p may be owing, it is assumed to be constant within the limits of the tropics. The formula used in page 287 is obtained by putting m for $\sin I \delta\lambda$, n for $\cos I \delta I$, and $a + p$ for $\delta\Delta$ in equation (A).

Instead of forming a separate equation from this formula for every different value of a , the whole number of observations is divided into twelve groups, the mean of the values of a in each group is considered to correspond to the day nearest the numerical mean of the days of observation in the group, and λ and Δ are taken for the mean noon of the mean day from the Nautical Almanac. In this manner twelve different equations were formed. The rest of the calculation for finding m , n , p , and the mean errors of the Sun's Tabular R.A., the Tabular value of the obliquity, and the assumed R.A. of the fundamental stars, requires no explanation additional to that given in pages 287 and 288.

The *Occultations of fixed Stars by the Moon and the Calculation of the Occultations* in pages 291—304, are sufficiently explained by the statements in pages xxviii and xxix, the same formulæ being used as for the Occultations of 1849.

OBSERVATIONS OF 1851.

The explanation of the printed observations of 1851 is in general the same as that of the observations of 1849 and 1850.

I. *Apparent Right Ascensions observed with the Transit.* Pages 306—341.

The Table of intervals of the wires from the mean of all in p. xxix was used throughout 1851.

The corrections for the forms of the Transit-pivots, which have been applied to the mean of the wires previous to the reduction to the meridian, were adopted on the following considerations. The details of the measures recorded in 1850 and their calculated results are given in pp. xxx—xxxiv. These apply only to the position of the Transit in which the Illumination is East. No measures were taken for the other position of the instrument until an attempt was made in 1852, which proved to be useless on account of the unsteadiness of one of the caps on which the dots are engraved. This cap had been clamped to a cylindrical piece of brass, which was screwed, but not firmly, to the

end of the pivot for the purpose of supporting the apparatus by which the Illumination is regulated. On discovering the cause of failure, the cap was altered so as to admit of being clamped to the pivot itself. Owing to the pressure of other occupation the next measures were deferred till April of 1854, when two sets were taken for each position of the instrument. The details of these measures will be given in a subsequent volume: it will suffice for the present purpose to adduce such of the results as are contained in the subjoined Table.

The first four N.P.D. apply to Polaris and δ Ursæ Minoris below and above Pole.

The corrections adopted for 1851, 1852, and 1853, Illumination East, were deduced by simply distributing the differences between those of 1850 and 1854 in equal parts over the intermediate years. The adopted corrections of 1850, Illumination West, which have already been exhibited in p. xxxiv, were calculated on the following principles. As the change of the values from 1850 to 1854, assuming the measures to be exact, can only be ascribed to the wear of the pivots, and as in that interval the Illumination was West about double the time it was East, the effects of the wear were assumed to be in the same proportion. Now it will be seen by the above Table that if we except positions near the Pole, where tenths of seconds must correspond to very small arcs, the changes of the corrections for Illumination East from 1850 to 1854 do not in any case differ more than $0^s,01$ from the mean value $0^s,14$. The mean change for Illumination West would accordingly be $0^s,28$. And as from the nature of the case the correction must continually increase in the same direction, it has been assumed that in 1850 it was *less* by the above mean quantity than in 1854. The differences for Illumination West, as exhibited in the above Table, are somewhat larger than twice the corresponding differences for Illumination East. This is owing to the circumstance that the calculation which was employed took into account the actual change of *level* error by wear of material in the four years, it having been ascertained by further observation that $L_e - l$ changed from $+0'',36$ to $0'',01$ and $L_w - l$ from $-1'',85$ to $-2'',65$ in that interval. (See p. xxxii.) As the latter change is rather more than double the other, the above mean quantity was raised to $+0^s,30$. This quantity is the assumed increment of correction from 1850 to 1854 for Polaris and δ Ursæ Minoris.

The corrections for both positions of the instrument in 1850 having been calculated in the manner above described, the adopted corrections for 1851 are those of 1850 *plus* one-fourth the increments from 1850 to 1854, and are therefore as follows:

N.P.D.	Correction Illumination East.	Correction Illumination West.	N.P.D.	Correction Illumination East.	Correction Illumination West.
-41,2	+0,16	+0,43	70	+0,26	+0,10
-39,3	+0,09	+0,38	75	+0,29	+0,05
-36,3	-0,17	+0,38	80	+0,32	+0,03
-34,4	-0,22	+0,34	85	+0,34	+0,05
+30	+0,04	+0,14	90	+0,34	+0,10
35	+0,08	+0,12	95	+0,32	+0,13
40	+0,10	+0,12	100	+0,30	+0,13
45	+0,13	+0,15	105	+0,30	+0,16
50	+0,14	+0,12	110	+0,32	+0,17
55	+0,16	+0,10	115	+0,34	+0,17
60	+0,19	+0,09	120	+0,35	+0,19
65	+0,22	+0,12	125	+0,37	+0,20

It may be remarked that although the considerations by which the corrections of 1850 for Illumination West were deduced from those of 1854 may be somewhat precarious, the reduction of the observations can be affected only in a very slight degree by any error in the adopted differences, because they vary very little from the mean value 0^s,30, and have, therefore, nearly the same effect as clock-error or difference of meridians. At the same time the difference of correction for difference of N.P.D., which is of chief importance in the reduction of the observations, was shown by the measures for Illumination East to be almost exactly the same in 1850 as in 1854, and we may hence conclude that the *law* of the corrections in 1850 for Illumination West was nearly the same as in 1854, and that it is very approximately expressed by the adopted corrections.

The following are the determinations of the collimation errors used in the reduction of the transits of 1851.

The value used from the beginning of the year to the end of Feb. 15, was that obtained on Dec. 6, 1850, omitting the correction +0^s,36, which, as explained in p. xxxiv, was applied by mistake to the level errors of 1850. The correct value of the collimation error is -1^s,08 + 0^s,36, or -0^s,72.

April 22, 23^h₂, the error of collimation was found by Mr Breen with the collimating eye-piece.

Illumination East.

Mean of 8 readings, micrometer-wire coinciding with its image	^{r.} 23,906
..... 10	<i>D</i> 23,822

Hence the value of *b*, the deviation of *D* eastward from the vertical plane, (see p. iii) is 17^s,06 × 0^s,084, or +1^s,43. And by levelling nearly at the same time *L_e* = +1^s,42. Hence *L_e* - *b* = -0^s,01, which, as explained in p. xxxii, is the adopted collimation error of *D*. Consequently the concluded error of collimation of the mean of the wires, inclusive of the correction for aberration, is 0^s,01 - 0^s,18 - 0^s,90, or -1^s,09, which to the nearest tenth of a second is used from Feb. 17.

May 6, 5^h. The Transit was reversed by Mr Breen. The South mark was very steady and well-defined, and the collimator placed in the North shutter-opening was steady throughout. A cross-wire for more accurate bisection was inserted by Mr Breen in the collimator. The pivots of the Transit had been well cleaned and oiled. The coincidence of the micrometer-wire with *D* was not taken after the reversion.

Illumination East.

Mean of 12 readings, micrometer-wire coinciding with <i>D</i>	^{r.} 23,823
..... 12	bisecting South mark 23,034
..... 12	bisecting North mark 22,631

Illumination West.

Mean of 12 readings, micrometer-wire bisecting North mark.....	24,731
..... 12 bisecting South mark	24,473
Reading for the line of collimation by South mark	23,754
..... North mark	23,681
..... true line of collimation	23,718
..... coincidence with D	23,823

As the readings increase towards the micrometer-head, which after the reversion was eastward, D was to the East of the true line of collimation by $0^{\circ}.105$. Hence correction for error of collimation of $D = \pm 17''.06 \times 0^{\circ}.105 = \pm 1''.79$, according as the Illumination is East or West. From this value, the correction, as it would be given by the collimating eye-piece, was inferred as follows. By calculations in p. xxxii,

$$\frac{a+b}{2} = L_w + 1''.85 = L_e - 0''.36;$$

and by levellings on May 5 and May 6, $L_e = +1''.30$ and $L_w = -0''.83$. Hence, the mean value of $\frac{a+b}{2}$ is $+0''.98$. The mean difference between simultaneous determinations of collimation error by the meridian marks and by the collimating eye-piece was deduced from two experiments made in 1847 (see Vol. XVII. pp. xxviii and xlvii) and one in 1849 recorded in p. v of this Introduction. If c be the collimation error, Illumination East, by the marks, and c' that by the collimating eye-piece, then, c' being equal to $\frac{a-b}{2}$, we have the following results:

Date.	a	b	c'	c	$c'-c$
1847 Feb. 11	$+1''.07$	$-4''.13$	$+2''.60$	$+3''.27$	$-0''.67$
Dec. 28	$-0''.31$	$-4''.46$	$+2''.08$	$+3''.29$	$-1''.21$
1849 Aug. 24	$+3''.29$	$+2''.39$	$+0''.45$	$+1''.01$	$-0''.56$

The mean value of $c'-c$ is $-0''.81$, which being applied to the above collimation error of D for Illumination East, gives $\frac{a-b}{2} = +1''.79 - 0''.81 = +0''.98$. Hence

$$a = \frac{a+b}{2} + \frac{a-b}{2} = +1''.96;$$

and as it has been shown that in consequence of the corrections for the forms of the pivots, the collimation error of D to be used for Illumination West is $L_w - a$, its value is $-0''.83 - 1''.96$, or $-2''.79$. Hence, as above, the concluded collimation error

$$= -2''.79 - 0''.18 + 0''.90 = -2''.07.$$

The value $-2''.4$ employed from May 6 to July 29 was obtained through a mistake in calculation: the difference is too slight to affect sensibly the reduction of the observations.

August 27, $23\frac{1}{2}^h$, I obtained the error of collimation by the collimating eye-piece. The wire D was so close to its image that the two were judged to be in contact, and the micrometer-wire was placed as nearly as possible so as to be bisected by the line of contact.

Illumination West.

Mean of 6 readings, micrometer-wire coinciding with its image	23,837
..... 6 D	23,871

Hence $a = +0''.034 = +0''.58$ in arc. And by levelling nearly at the same time $L_w = -1''.95$. Consequently, $L_w - a = -1''.95 - 0''.58 = -2''.53$, which is the adopted error of collimation of D , and the concluded error of collimation $= 1''.95 - 0''.18 + 0''.90 = -1''.81$. This correction is used from August 2 to the end of the year, the foregoing value of $L_w - a$ being little different from the preceding one, and from the next following, which was not obtained till April 7, 1852.

Level Errors in 1851.

* * In the reduction of the observations the above values of level error are taken to the nearest tenth of a second.

The level error of April 21, which was used on April 18, 19, and 21, is omitted by mistake in p. 316. The result of the levelling of Aug. 27 was confirmed by trial an hour after. The levelling on Dec. 10 was unsatisfactory, the bubble changing and the air of the Transit-room being in motion. On this account the levelling was repeated the next day. On Dec. 23, eight sets of readings were taken, six being the usual number. The level error used from Dec. 20, + 1",0, is that given by the last six readings.

The following is a list of corrections for the apparent inequality of the radii of the pivots, calculated in the manner explained in Vol. X. p. xxviii, and continued from those given in p. li of Vol. XVII.

Date of Reversion.	Correction Illum. E.	Date of Reversion.	Correction Illum. E.	Date of Reversion.	Correction Illum. E.
1849, Feb. 28 - 0,45	1850, Apr. 13 - 0,59	1850, July 16 - 0,41
Aug. 24 - 0,51	May 15 - 0,53	1851, May 5 - 0,49
1850, Apr. 1 - 0,57*	June 19 - 0,57		

* The level error being supposed constant from April 1 to April 8.

The above values indicate decidedly an increase in the apparent inequality of the pivots since the end of 1847, the greatest part of which is probably due to the wear of the pivots at the points to which the feet of the level are always applied, the Telescope being horizontal and looking southward during each levelling. No use has been made of the above corrections, the effects of the forms of the pivots, both on the position of the Transit and on the indications of the level, being considered to be fully taken into account in the corrections calculated in the manner explained in p. xxxii.

Calculation of Azimuth Errors in 1851.

The assumed mean R.A. have been deduced from the mean R.A. concluded from the observations of 1850 in the manner stated in p. xii. The mean excess above the R.A. of the Nautical Almanac (excluding Polaris and δ Ursæ Minoris) is +0^s,090, which is 0^s,001 greater than the mean excesses of the assumed R.A. of 1849 and 1850.

On April 9, no clock-stars having been observed with the Moon, δ Geminorum was used for clock-error, the R.A. of the Nautical Almanac being corrected by +0^s,09.

The following processes were adopted for eliminating errors arising from difference of personal equation. Observations of Mr Breen (B) and Mr Todd (T) in no instance occur in the same group; but when a clock-rate was to be inferred from observations of these two observers in different groups, an allowance for difference of personal equation, (which appeared to be a variable quantity), was made as nearly as it could be by estimation. Whenever such allowance was made, the amount is given in the notes. As it appeared from what is stated in page xiv that the difference of personal equation of T and myself (C) was very small, no allowance was made for it in calculating either the rate or the error of the clock in the mixture of the observations of C and T which occur from Aug. 3 to midnight of Aug. 18. Two clock-errors of T, deduced from observations on Aug. 13 and Aug. 18 under bad circumstances and put in brackets, were not made use of. Subsequently to the above date the observations of C and T are reduced independently, excepting that the clock's rate is inferred from the observations of one of the observers, or is a mean derived from two rates for the same epoch given by their observations taken separately. T's observation of the Sun on Sept. 6 was necessarily grouped with the preceding observations of C without taking account of difference of personal equation.

The difference of personal equation of C and T, as inferred from the separate reductions of their observations, was 0^s,04 on Aug. 21, 0^s,08 on Aug. 23, and 0^s,15 on Sept. 13, T observing earlier than C by these quantities. As the observations were reduced independently, these differences are actually taken into account, so that the note to the transits of β Aquarii and Neptune on Aug. 21 was needless, and the clock-error by the star should not have been put in brackets.

The transits from Aug. 26 to Sept. 4 marked by the Italic *B*, were taken by Mr John William Breen, to whom I gave permission to observe for the sake of practice. These observations and those of C in the same interval are reduced independently, in the manner already stated with reference to the observations of C and T, excepting that *B*'s observations on Aug. 30 are corrected by +0^s,02 for difference of personal equation, because on that day he observed only one clock-star. This correction was ascertained by the following comparisons of Clock-errors reduced to the same epochs:

Day of Observation.	Clock's Loss by B.	Number of B's Observations.	Clock's loss by C.	Number of C's Observations.	Excess of C's Clock-error.	Assumed Weight.
Aug. 28	18,22	3	18,14	4	-0,08	3
.. 30	20,88	1	20,73	3	-0,15	1
Sept. 3	27,15	6	27,21	3	+0,06	4

Taking the weights into account the mean excess of the clock's loss by C is $-0^s.02$, that is, C observed *later* than B by $0^s.02$.

The corrections from the apparent to the mean R.A. in pages 344—357 were calculated in the same manner as those of 1849 (see pages xv and xxi), and the Annual Variations in pages 348—357 were calculated as stated in p. xxii. excepting that the Logarithmic constant of the formula was 0,12612.

II. *Apparent North Polar Distances observed with the Mural Circle.* Pages 360—388.

The following Table contains the results of microscope readings taken in 1851 to ascertain the corrections for Runs.

Time of Observation, 1851.	Excess of micrometer-reading for preceding division above micrometer-reading for following division, for each microscope.						Corr. for Runs for 5'.	Temperature.		Time of Observation, 1851.	Excess of micrometer-reading for preceding division above micrometer reading for following division, for each microscope.						Corr. for Runs for 5'.	Temperature.

The Runs of Oct. 9 ^{4h}, are not used because after they were taken an irregularity was noticed in the reading of Microscope E. owing apparently to disarrangement of the wires caused by pushing the eye-piece too far in to suit the observer's sight. The Runs of Oct. 9, ^{23h}, were taken after the eye-piece had been pulled out a little. The Run of Microscope E was found at 0^h of Oct. 10 to be $+1^s.3$, shewing that the readings were steady. Between Oct. 17 and Oct. 22 the Microscope was removed to be rectified.

The correction for Runs used from June 9 is the mean of the three obtained on June 14 and 17; that used from Nov. 10 is the mean of the three of Nov. 12, 13, and 15; and that used from Nov. 18 is the mean of those of Nov. 19 and 21.

The following measures were taken by Mr Todd to determine the value of $1''$ of the micrometer of the Circle Telescope.

The measures of Oct. 27 and Nov. 13 were taken by means of the meridian mark in the usual way. For those of Nov. 12 the collimating eye-piece was used in the manner described in p. xlv. The corrections for Runs, (which on Oct. 27 and Nov. 13 were negative), were derived from the values for $5'$ given in the foregoing Table. The micrometer-readings for coincidence of the micrometer-wire with its image on Nov. 12 are the means of 8, 8 and 12 readings respectively, and the microscope readings are the means of two sets of bisections. The value of the micrometer-revolution given by a comparison of the first and third measures of that day is $20'',836$. The mean of the differences of Oct. 27 gives $1''=20,852$, and the mean of those of Nov. 13 gives $1''=20'',830$. It was thought preferable upon the whole to adopt the mean of the two last values, viz. $20'',841$.

It may be remarked that since $20''$ is the micrometer-reading for the middle of the field, the measures of Nov. 13 shew that the value of the micrometer-revolution is the same, whether the micrometer-readings correspond to positions of the wire in the upper half, or in the lower half, of the field.

On May 23 Mr Todd attempted to determine the value of the micrometer-revolution by bisections of Polaris, allowing for its change of N.P.D. by diurnal motion. The reductions of these observations (in p. 373) shew that the bisections were not sufficiently accordant for this purpose.

Zenith Points obtained in 1851 with the Collimating Eye-piece.

On Feb. 9, the mercury was unsteady and the wire and its image could not both be well seen; and on Oct. 9, at 23^h, the microscope readings were doubtful, the circle dripping with moisture. These notes were inadvertently omitted in pages 363 and 382.

The Runs used in calculating the Zenith Points of 1851 are the same as those adopted for the reduction of the observations, and not as in former years the Runs obtained with the Telescope directed to the Nadir. On March 1 and on Oct. 9 the Microscopes were re-adjusted, the Circle having been removed from the wall. A Zenith Point was taken on March 2 before the adjustment of the wires, and could not therefore be used. That taken by myself on Oct. 9, at 4^h, soon after replacing the Circle, is not used. The Zenith Point of Oct. 10, being apparently affected by an irregularity of Microscope E to the same amount as the concluded Circle readings for the observations of that day, is only used for those observations. As this discordance was not perceptible before or after Oct. 10, the second of the Zenith Points obtained on Oct. 9 is used during Oct. 11—17. The mean of the Zenith Points of Sept. 16 and 17 is adopted for Sept. 13—19, and the mean of the three taken on Oct. 22 is used on Oct. 22 and 24. Of those taken Oct. 27, only the first is used, the micrometer-readings shewing that for the other two the micrometer-wire was too distant from the centre of the field. (These two ought not to have been inserted in p. 383.) For the same reason no use was made of the second and third Zenith Points of Nov. 12, which were calculated from measures taken on that day for the determination of the value of the micrometer-revolution, the particulars of which are already given.

The corrections from the Apparent to the Mean N.P.D. and the Annual Variations in pages 390—401, were calculated in the same manner as those of 1849, excepting that the logarithmic constant of the formula for the Annual Variation was 1,30221.

Mean Excess for each Star of the adopted Zenith Points above the Zenith Points given by direct and reflection observations in the year 1851.

The curve which represents the law of discordance (described as stated in p. xxiii) has nearly the same form as in previous years, but the zenith point for the zenith direction by the collimating eye-piece is greater than that by direct and reflection observations of stars by the mean quantity 0",56, by which, consequently, the zenith direction is apparently more *southward*. The following is a list of the excesses of the zenith point for zenith direction by the collimating eye-piece for the several years during which this instrument has been in use.

Year	1845	1846	1847	1848	1849	1850	1851
Excess	...	+ 0",02	— 0",08	+ 0",13	+ 0",71	...	— 0",41*	+ 0",44	+ 0",56

* By mistake this quantity has a positive sign in p. xxiv.

These differences follow no obvious law, and probably are in part due to errors of graduation, which may be assumed to be eliminated in the zenith point deduced from the observation of a considerable number of zenith stars.

It should be observed that the corrections in the above Table for Zenith Distances exceeding 65° are uncertain.

* As the observer thought the noted time was 1^s short, — 0,8 has been used.

The apparent R.A. of those stars which are not fundamental were taken from the section of Moon-Culminating stars in the Nautical Almanac. As the above results shewed that the adjustments of the Circle were very little altered by its removal from the wall on March 1 and on Oct. 9, and that they remained nearly the same as in the latter half

of 1850, these observations were used collectively to obtain by graphical construction the following mean values:

N.P.D.	Interval from meridian to middle wire.	N.P.D.	Interval from meridian to middle wire.	N.P.D.	Interval from meridian to middle wire.
60	-1,90	85	-1,40	110	-0,85
65	-1,84	90	-1,30	115	-0,76
70	-1,72	95	-1,20	120	-0,66
75	-1,63	100	-1,09		
80	-1,52	105	-0,96		

These intervals are taken into account in the reduction of observed N.P.D. of the Moon to the meridian, as explained in p. 1.

In addition to the above Circle transits, others were taken unaccompanied by comparisons with Hardy, which were employed to determine the error of Molyneux for reducing observations of Polaris and δ Ursæ Minoris to the meridian. It has not been thought worth while to insert these observations: the foregoing results shew that the Circle was adjusted to the meridian nearly enough to be used for this purpose.

III. Measures of Diameters of the Sun and Moon, and Right Ascensions and North Polar Distances of the Sun, Moon, and Planets, from observations in 1851. Pages 404—412.

The general explanation of the collection of results contained in this Section, may be gathered from the explanations already given relative to the corresponding observations of 1849 and 1850. The following are the only additional particulars that require to be mentioned.

The Greenwich Mean Solar Times, the Tabular R.A. and N.P.D., and the Semi-diameters and Parallaxes of the Sun and Moon were obtained in the same manner as those for the Observations of 1850.

Metis. The observed R.A. and N.P.D. are compared from January 22 to February 26 with the Ephemeris in p. 649 of the Nautical Almanac for 1854, the Log. distances for parallax being deduced from the Ephemeris in the *Berliner Jahrbuch* for 1853, p. 365. To include January 22 and 23, and February 26, the Ephemerides were extended by differences. The Greenwich Mean Time for January 22 was calculated from the Tabular R.A. corrected by $+3^s.5$. For the observations subsequent to February 26, the Tabular quantities were specially calculated from the Elements used for the computation of the Ephemerides, and given in pages 640 and 371 of the respective works, aberration being taken into account by means of the approximate Ephemeris in p. 648 of the Nautical Almanac.

Iris. For the observations to October 14 inclusive, the Ephemeris in p. 647 of the Nautical Almanac for 1854, and that in p. 359 of the *Berliner Jahrbuch* for 1853, were made use of, the Ephemerides being extended one day by differences. For the remainder of the observations the Tabular values were calculated directly from the Elements in pages 640 and 371 of the above works, the Greenwich Mean Time for the observation of November 14 being first interpolated from Greenwich observations on November 12 and 15, and the Cambridge observations of November 18 and 21. Aberration was taken into account by means of the ten-day Ephemeris of the Nautical Almanac.

Hebe. The Tabular R.A. and N.P.D. were taken from p. 651 of the Nautical Almanac, and Log. distance from p. 357 of the *Berliner Jahrbuch*. The R.A., N.P.D., and Log. distance for comparison with the observed place of June 19, were computed directly from the Elements, but through inadvertence the observed N.P.D. and the comparison with calculation have been omitted. (See the Addenda to the Introduction.)

Parthenope. The Tabular quantities were interpolated for the Greenwich Mean Times corrected for aberration, from the Ephemeris by Luther and Vogel in the Monthly Notices

of the Royal Astronomical Society, Vol. XI. p. 210. The Greenwich Mean Time of Nov. 20 was calculated from the R.A. of that day, as deduced from the observed R.A. of Nov. 22, 24, 25 and 26 by differences.

Astræa. For the observations to May 14 inclusive, the Tabular quantities were taken from the Nautical Almanac of 1854 (p. 655) and the *Berliner Jahrbuch* of 1853 (p. 355), the Ephemerides being extended one day by differences; and for the remaining observations they were computed for the respective Greenwich Mean Times from the Elements, aberration being allowed for by means of the ten-day Ephemeris.

Irene. The Tabular places and Log. distance were computed from the following Elements of Sig^r. Virgilio Trettenero in the *Astronomische Nachrichten*, Vol. XXXVI, N^o. 852, col. 192:

Mean Anomaly 1851, May 21,0 Greenwich Mean Time	45 . 36 . 16,21	} Mean $\mathcal{A}eq^x$. 1851, May 21, 0.
Longitude of Perihelion	178 . 46 . 55,59	
Longitude of Ascending Node	86 . 49 . 6,26	
Angle of Eccentricity	9 . 42 . 55,81	
Inclination	9 . 6 . 40,46	
Logarithm of Mean Distance	0,4123975	
Daily increment of Mean Anomaly	853",90626	

The aberration corrections were deduced from the computations.

Eunomia. The Tabular quantities were computed from the following Elements by Mr George Rümker in the *Astronomische Nachrichten*, Vol. XXXVI, N^o. 859, col. 307:

Mean Anomaly 1851, Dec. 31,0 Berlin Mean Time	314 . 21 . 55,5	} Mean $\mathcal{A}eq^x$. 1851, Dec. 31,0.
Longitude of Perihelion	27 . 53 . 58,3	
Longitude of Ascending Node.....	293 . 54 . 30,0	
Angle of Eccentricity	10 . 49 . 33,4	
Inclination	11 . 43 . 59,6	
Logarithm of Mean Distance	0,4221645	
Daily increment of Mean Anomaly	825",58134	

The Greenwich Mean Time of Aug. 21 was interpolated from those of Aug. 19, 20 and 22. The aberration corrections were deduced from the computations.

Hygeia. The Tabular quantities to Oct. 10 were taken from the Nautical Almanac (p. 657) and the *Berliner Jahrbuch* (p. 367), those for Sept. 12 being obtained by extending the Ephemerides by differences. The remainder were specially calculated from the Elements, and corrected for aberration by means of the ten-day Ephemeris. The Greenwich Mean Times of Sept. 12, 19, Oct. 2 and 14, were deduced from the Tabular R.A. corrected for excess above the observed R.A., the Ephemeris being extended by differences to obtain the Tabular R.A. for Sept. 12 and Oct. 14.

Neptune. The Tabular places were interpolated from Walker's Ephemeris in the *Astronomical Journal*, Vol. I. N^o. 24, p. 185, and the parallax was calculated by means of the values of Log. Δ added to the Ephemeris. For those days on which the Planet was not observed in R.A. the Greenwich Mean Times were deduced from the R.A. of the Ephemeris.

The number of wires at which each transit of a Planet was taken, (inserted in the second column), has been added to aid in forming a judgment of the weights to be given to the separate observations.

The calculation of the *Position of the Ecliptic* and of the *Mean Error of the Assumed R.A. of the Fundamental Stars* (pp. 413 and 414) was performed exactly as in the preceding year, and needs no additional explanation. It may be remarked that the value obtained for the error p seems to shew that the correction applied for discordance of Zenith Points within the Tropics was too large.

The *Occultations of Fixed Stars by the Moon* were reduced in the same manner as those of 1849.

All the observations in this Volume were originally recorded in pencil writing in small memorandum books, which are carefully preserved for future reference.

ADDENDA.

WHILE the Observations of 1851 were in course of printing it was found that there were several points relating to the stars that remained to be determined, which from their positions in the heavens could not be settled at the time. Some of these are mentioned in the notes to the Catalogues of Concluded R.A. and N.P.D. The determinations were subsequently made as follows.

P. 331. The Transit observation of 29 Aquarii on Sept. 12 was accompanied by the remark, '*sp* of a close double, Mag^s. equal.' This was omitted in the Notes as being thought liable to uncertainty on account of the small altitude of the star. But by an observation with the Northumberland Telescope 1857 Aug. 17, the two stars were found to be in the *sp* and *nf* quarters, about 3''' apart, and to be each of Mag. 6.

P. 355. In the Note to N^o. 529 it is stated that the concluded R.A. was less than that of Argelander by about 1^s. The R.A. of Argelander was confirmed by a Transit observation taken 1857 Sept. 3.

P. 390, N^o. 2. The N.P.D. of the Cambridge Observation was confirmed by an Equatorial observation taken 1857 Aug. 17, and Bessel's N.P.D. is therefore 3' too small.

P. 399, N^o. 628. The approximate mean R.A. 1851,0 of this star, as determined by an Equatorial comparison 1857 Aug. 17 with Argelander Z. 308 N^o. 42, is 18^h. 14^m. 33^s.

P. 399, N^o. 689. The mean R.A. 1851,0 was ascertained Aug. 14, 1857 by an Equatorial comparison with Bessel xx. 932 to be 20^h. 37^m. 42^s.

P. 400, N^os. 718 and 719. The mean R.A. 1851,0 as deduced from an Equatorial Comparison 1857 Aug. 17 with Bessel xxi. 280, is 21^h. 8^m. 52^s, as in the Catalogue.

P. 400, N^o. 741. The mean R.A. 1851,0 was found by an Equatorial comparison with ϵ Capricorni on Aug. 17, 1857, to be 21^h. 28^m. 48^s. Its magnitude as seen in the Northumberland Telescope was considered by Mr Breen to be 10.11.

Also the following omissions relating to observations of Planets were discovered after the sheets were printed off.

P. 384, Nov. 1. An observation of Hygeia should have been inserted after that of Neptune. It was supposed not to apply to the Planet and was consequently rejected. The microscope readings were 0'.13",3, 11",2, 12",3, 12",9, 6",0, 12",3; the concluded Circle reading, 114°.15'.11",38; Barom. 29ⁱⁿ.500; Thermom. Int. 39°,0, Ext. 36°,5; Refraction, 65",22; and Apparent N.P.D., 85°.38'.13",59. The observation is taken into account in p. 411.

P. 410. The following quantities relating to the observation of Hebe on June 19 should have been inserted. Seconds of Tabular R.A., 36°,94; Excess of Tabular R.A., -0°,90; Parallax, 5",20; Geocentric N.P.D., 97°.0'.0",84; Seconds of Tabular N.P.D., 58",47; Excess of Tabular N.P.D., -2",37.

TABLES

USED IN THE REDUCTION

OF THE TRANSIT AND CIRCLE OBSERVATIONS,

AS EXPLAINED

IN THE FOREGOING INTRODUCTION.

TABLE I.

General Table of the Coefficients of the Collimation, Level, and Azimuth Errors, for the reduction of the Transit observations.

The N.P.D. of the object observed = δ , and its Zenith Distance = z .

* * See page xii.

The above Table was calculated for the mean N.P.D. of the Stars Jan. 1, 1860, and may be used fourteen years before or after that date.

The following are the coefficients for Polaris, δ Ursæ Minoris, and 51 (Hev.) Cephei, calculated for the year 1850 + n .

Star.	$\frac{1}{15 \sin \delta}$	$\frac{\cos z}{15 \sin \delta}$	$\frac{\sin z}{15 \sin \delta}$
Polaris.....	+ 2,56721 + 0,009593 $\times n$	+ 2,06905 + 0,007584 $\times n$	- 1,51973 - 0,005879 $\times n$
Polaris SP.....	- 2,56721 - 0,009593 $\times n$	- 1,98736 - 0,007584 $\times n$	+ 1,62511 + 0,005879 $\times n$
δ Ursæ Minoris.....	+ 1,12383 + 0,000165 $\times n$	+ 0,92746 + 0,000131 $\times n$	- 0,63468 - 0,000101 $\times n$
δ Ursæ Minoris SP...	- 1,12383 - 0,000165 $\times n$	- 0,84576 - 0,000131 $\times n$	+ 0,74006 + 0,000101 $\times n$
51 (Hev.) Cephei.....	+ 1,39149 - 0,000365 $\times n$	+ 1,13929 - 0,000289 $\times n$	- 0,79891 + 0,000224 $\times n$
51 (Hev.) Cephei SP.	- 1,39149 + 0,000365 $\times n$	- 1,05760 + 0,000289 $\times n$	+ 0,90428 - 0,000224 $\times n$

* * For a direct observation the sign of the Correction is + North of the Equator and above the Pole, and - South of the Equator and below the Pole. For a reflection observation the signs are the opposite to those for a direct observation.

TABLE V.

Corrections for change of N.P.D. of the Sun and Planets in one interval from the middle wire, for given declinations and given horary variations of declination.

* * See page xviii.

* * When the sign of the horary variation of declination in the Nautical Almanac is -, the sign of the correction is + before passing the middle wire and - after passing. When the sign of the horary variation of declination is + in the Nautical Almanac, the sign of the correction is - before passing the middle wire and + after passing.

TABLE VI.

Table of corrections for reducing the Tabular R.A. and N.P.D. of the Sun, Moon, and Planets, from the Greenwich to the Cambridge transit.

* * See page xxvii.

* * The correction to be applied to the Tabular R.A. has the *opposite* sign to that of the variation of R.A. for one hour in the Nautical Almanac.

The correction to be applied to the Tabular N.P.D. has the *same* sign as that of the variation of declination for one hour in the Nautical Almanac.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,362, -26°,890, -13°,537, -0°,065, +13°,616, +26°,877, +40°,362.

(a) Wire IV was written down 8,9. (b) The Planet faint, but observed satisfactorily: no object near it. (c) The temperature on Jan. 2 at 11h was at 25°. (d) Extremely unsteady. (e) 'Very good.' (f) The eye-piece misty and the field not well illumined: the sky had just become clear. (g) No definition. (h) The Planet bright and the observation satisfactory. (i) Fog, and the star too flaring and unsteady for accurate observation. (k) Seen with difficulty through cloud. (l) Corrected by -1". (m) Between Jan. 5 and Jan. 15 the temperature rose 9°. The clock's losing rate appears to increase when the Transit room is closed on account of cloudy weather. (n) Hurried, the observer being delayed at the Northumberland Dome. (o) The noted times have been increased by 1". (p) Cloudy during most of the evening. (q) Very faint. The observation has been corrected by -1".

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40',362, - 26',890, - 13',537, - 0',065, + 13',616, + 26',877, + 40',362.

(a) Very high wind all the evening. (b) Rather faint. (c) Temp. at 46°. (d) 'The following of two.' (e) 'Extremely faint: Mag. 10.' Possibly not the star observed Feb. 8. (f) Very faint. Two smaller objects followed. (g) Very irregular intervals. (h) Greatly diffused. (i) Misty cloud all over the sky. (k) Between Jan. 23 and Jan. 26 the temperature fell 6°. (l) The counting being 1' in advance, the two last wires have each been diminished 1'. (m) Faint: clouds just clearing off after rain. (n) Wires were lost by casual displacements of the Telescope, to which it was liable on account of too great counterpoise action. (o) The field not sufficiently illuminated. Wire IV has been increased 1'. (p) Cloudy. (q) 'The preceding of two of nearly equal magnitude.'

RIGHT ASCENSIONS OBSERVED WITH THE TRANSIT IN THE YEAR 1849.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°.362, -26°.890, -13°.537, -0°.065, +13°.616, +26°.877, +40°.362.

- (a) 'A star of Mag. 7.6.' See Jan. 23. (b) One of Mag. 5.6 preceded. (c) A fainter star of greater N.P.D. preceded. (d) Very unsteady.
 (e) Much radiation. The preceding star was brighter than the other and of greater N.P.D. (f) These stars were judged to be of the same magnitude.
 (g) Wires III and IV have been increased 1' conjecturally. (h) The catalogue number is that of Oeltzen's reduction of Argelander's Zones. (i) Used as a comparison star in an observation of Flora 1848 April 29, and considered to be of Mag. 8. (k) Perhaps the star observed with the Circle Feb. 10; if not, the N.P.D. is uncertain.
 (l) H. C. 13230 appears to be the same star. (m) No definition. (n) 'Good.' (o) Mag. 9.10. (p) 'Mag. 8.' (q) Wire VI was written down 4.0. This is not the star intended to be taken, and the N.P.D. is uncertain. (r) Wire II was set down 4.7: the mistake was noticed at the time of observation.
 (s) Another star near. (t) An object of greater N.P.D. passed wire VII at 36m. 3.1. (u) 'Mag. 8.9.' (v) Very faint: after 10h the sky was very cloudy. (y) Of Mag. 8, and equal to another of less N.P.D. by W. (z) 'Not of Mag. 5.6.' (aa) 'Very faint: of the 11th magnitude.'

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,362, -26°,890, -13°,537, -0°,065, +13°,616, +26°,877, +40°,362.

(a) Accompanied by a much smaller star. (b) Another of less N.P.D. was noticed. (c) Of the 8th magnitude. (d) 'The second in brightness of a great number.' (e) Beautifully defined. (f) The Telescope unsteady from the cause mentioned Jan. 30. This remark applies to most of the observations taken previous to the reversion of the instrument on Feb. 27. (g) Faint and diffused. (h) Faint. (i) Mist. (k) The N.P.D. of these stars are uncertain: the latter was taken for H. C. 9656. (l) Very faint: Mag. 9,10. (m) Mag. 9,10: the middle star of three. (n) Of the 6th magnitude by Bessel, of the 5th by H. C. Not in other catalogues.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adapted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°,362, - 26°,890, - 13°,537, - 0°,065, + 13°,616, + 26°,877, + 40°,362.

(a) Faint from cloud. (b) Very faint. 'The north-preceding of two.' The other is Bessel v. 12. (c) Very unsteady. (d) Very faint and difficult to observe on account of cloud. (e) Faint. (f) Extremely faint. (g) Great radiation. (h) Bad definition. (i) 'The southern and brighter of two.' The noted times have been diminished 1^m. (k) Wire IV was set down 54,2. (l) Badly defined and faint. (m) Difficult to observe, so diffused. (n) Extremely faint and unsteady. (o) 'Another precedes.' (p) Wires I and II lost by the motion of the Telescope. See Jan. 30. (q) Clouds passing and the planet very faint. The intervals are irregular. (r) Had a disk. (s) 'The southern and brighter.'

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,362, -26°,890, -13°,537, -0°,065, +13°,616, +26°,877, +40°,362.

(a) The N.P.D. is uncertain. See note to B.A.C. 2118 Feb. 12. (b) 'Mag. 6,7.' This is Bessel vi. 1074, the N.P.D. of which appears to be 10' too small.
 (c) Cloudy. (d) The clouds had just cleared off after heavy rain, and the stars appeared distorted blotches of light. (e) 'The north-preceding of two.'
 (f) Blazing. (g) 'Good.' (h) 'A brighter south-following.' (i) Disturbance. (k) The N.P.D. is uncertain. (l) Mag. 9,10. (m) 'Very faint: of 11th Mag.' Mag. 9 by Bessel. (n) Great scintillation. The temperature Feb. 26-28 ranged between 35° and 31°, producing apparently an acceleration of the clock's rate. (o) 'The south-preceding of two equal.' (p) Mag. 9. 'The intervals are irregular.' (q) Very unsteady.

RIGHT ASCENSIONS OBSERVED WITH THE TRANSIT IN THE YEAR 1849.

ILLUMINATION EAST. From Feb. 28, ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,362, -26°,890, -13°,537, -0°,065, +13°,616, +26°,877, +40°,362. From Feb. 28, -40°,362, -26°,877, -13°,616, +0°,065, +13°,537, +26°,890, +40°,362.

(a) Very unsteady. (b) Scarcely visible on account of cloud. (c) Cloudy. (d) Faint. (e) 'Mag. 10,11.' (f) 'Mag. 6.' Taken for H. C. 15112 which precedes about 1^m. (g) Corrected by +15". (h) Bad definition. The sky just clear after a great fall of snow. (i) No clock star could be obtained. The losing rate 0,02, used from 0^h of March 1, is that given by comparing the clock-errors of Feb. 28 and March 2. (k) The temperature was at 40° at 11^h of March 2. (l) Clouds passing. (m) No other object visible. (n) Very faint.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°, 362, - 26°, 877, - 13°, 616, + 0°, 065, + 13°, 537, + 26°, 890, + 40°, 362.

March 8, 23^h, Hardy was put forward 1^m.

(a) Very diffused: after snow. On March 8 the Temperature was about 33°, having fallen 10° since March 5. (b) A mere patch of light. (c) Very bad definition. (d) The clock's rate at this time was irregular: the gain between March 8 and March 10 may be owing to putting the clock forward. The Temperature March 10 was about 33°. (e) At 8^h of March 17 the Temperature was 47°. (f) A smaller north-following. (g) So unsteady as to be scarcely visible. (h) The sky nearly overcast with thick fog. (i) Of Mag. 8,9. There is no object in the place of H. C. 14509. (k) Very unsteady and flaring.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.	Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,362, -26°,877, -13°,516, +0°,065, +13°,537, +26°,890, +40°,362.

(a) Faint: the sky not clear. (b) On March 24, the temperature fell to 30°. (c) No definition. (d) The last four wires have been corrected by -2°. (e) 'South-preceding.' The other component is brighter. (f) Corrected by +10°. (g) Diffused and extremely unsteady. (h) Seen at intervals with much difficulty on account of clouds. (i) Very cloudy. Snow falling at times this evening and the stars ill-defined. (k) Disturbance by noise. The noted times have been diminished 1°. (l) 'South-preceding of two.' (m) No definition and great motion. (n) 'Not good: observed hurriedly.' (o) 'Preceding of two.' (p) 'Good.' (q) Cloudy. (r) Extremely faint, scarcely bearing illumination. The observation was, however, satisfactory. (s) 'The south-preceding.' Temperature on this evening at 46°.

RIGHT ASCENSIONS OBSERVED WITH THE TRANSIT IN THE YEAR 1849.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°.362, - 26°.877, - 13°.616, + 0°.065, + 13°.537, + 26°.890, + 40°.362.

(a) Position of the observer very uncomfortable. (b) Wire III taken hurriedly. (c) Faint, but observed satisfactorily. The wires were lost by wrong setting. (d) 'North-preceding of two.' (e) Temperature this evening at 36°. (f) 'Barely perceptible.' (g) Clouded. (h) Flaring. (i) Diffused and unsteady. (k) No definition. (l) 'Only seen occasionally. The planet too faint to observe with any certainty.' (m) Corrected by -1', the counting being found to be 1' in advance. Bessel x. 522 has the same N.P.D. as this star, but greater R.A. by about 15°. (n) Interrupted by clouds. (o) The shutter in the way. (p) Temperature on this night, 32°. (q) 'The preceding of two.' (r) Flaring and unsteady. (s) 'Good observation.'

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°,362, - 26°,877, - 13°,616, + 0°,065, + 13°,537, + 26°,890, + 40°,362.

(a) 'Wire V not good.' (b) Irregular motion. (c) Extremely unsteady and badly defined. Observations this night were quite uncertain, the stars being very tremulous and without definition. (d) Faint. (e) Barely seen from cloud. (f) Cloudy. (g) Very faint. 'A brighter object of less N.P.D. followed.' The clock had been suffered to run down, and had not yet recovered its usual rate. (h) Had definition. (i) Very faint. (k) Unsteady and indefinite. Between May 23 and May 29 the minute hand of the clock was adjusted, having been left 4th slow after the clock was set going. (l) The noted times, which were not taken from the clock, have been corrected by -24". (m) 'Very good.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.	Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°, 362, - 26°, 877, - 13°, 616, + 0°, 065, + 13°, 537, + 26°, 890, + 40°, 362.

(a) Wires VI and VII have been diminished 30°.
(c) 'Preceded by a very faint star of less N.P.D.'
was at 41°. (f) Cloudy during these evenings.

(b) Between wires I and II the eye-end of the Telescope was slightly struck on the West side.
(d) Very faint. 'A brighter of greater N.P.D. preceded.'
(g) Very faint from cloud. (h) An undefined patch of light. (i) Clouded and badly defined.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°,362, - 26°,877, - 13°,616, + 0°,065, + 13°,537, + 26°,890, + 40°,362.

(a) Cloudy. (b) 'The following, and perhaps the brighter, of two of nearly the same N.P.D.' (c) Very faint. Wire IV was set down 32,0, and has been altered conjecturally. (d) Very cloudy: not observed to be double. The intervals are irregular. (e) 'A fainter of somewhat greater N.P.D. precedes &c.' The preceding star is Σ 341. (f) This is Bessel xviii. 37. (g) Very badly defined. (h) The intervals are very irregular. (i) Heavy cumuli continually passing. (k) On July 7 at 1h. 40m Mc Breen found that Hardy had stopped and set it going. It stopped again on the night of that day, and I subsequently discovered that the second-hand was liable to catch against the minute-hand at a certain hour. (l) The clock was set going at 17h. 19m sidereal time. Several observations, taken shortly after, were rejected on account of the uncertainty of the rate. (m) Well-defined. (n) Extremely faint. (o) Corrected by -1m. (p) Faint.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40',362, - 26',877, - 13',616, + 0',065, + 13',537, + 26',890, + 40',362.

(a) Faint. (b) Flashing. (c) Unsteady. (d) 'An equal one of less N.P.D. precedes, and a fainter follows.' (e) 'One of less N.P.D. followed about 11h.' (f) 'Hardly visible at times from cloud.' (g) 'Very faint and unsteady.' (h) 'The last three wires have been corrected by - 30'. (i) 'The brightest of several.' (k) 'One of greater N.P.D. precedes.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.
		I	II	III	IV	V	VI	VII		Collimation Error.	Level Error.	Azimuth Error.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40',362, - 26',877, - 13',616, + 0',065, + 13',537, + 26',890, + 40',362.

(a) 'Two of less N.P.D. precede.' (b) 'A brighter of greater N.P.D. precedes.' (c) Cloudy. (d) This is Argelander Zone 224, No. B.
 (e) Taken hurriedly. The intervals are irregular. (f) Corrected by - 1". The observer noted the error at the time. (g) Very faint from cloud.
 (h) 'Very good.' (i) 'Another object of nearly the same magnitude and R.A. and of less N.P.D.' The noted times have been diminished by 1". (k) Thick cloud.
 (l) Clouds passing. (m) Hid by clouds, and near the moon. (n) Very faint.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°,362, - 26°,877, - 13°,616, + 0°,065, + 13°,537, + 26°,890, + 40°,362.

(a) Cloudy. The noted time was 1^m greater. (b) 'Counting 1^s slow.' All except wires I and II have been increased 1^s. (c) Too faint for certainty.
 (d) Cloudy. (e) Unsteady. (f) 'A bright star of greater N.P.D. preceded.' (g) 'Rather brighter than a following star.' The second star is B.A.C. 6727.
 (h) The stars this night were badly defined and unsteady. (i) 'Counting 1^s fast.' Wires VI and VII have been diminished 1^s.
 (k) 'Very good.' (l) 'An equal star of less N.P.D. followed.' (m) 'The southern of two.'

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',362, -26',877, -13',616, +0',065, +13',537, +26',890 +40',362.

(a) Cloudy at the last wires. (b) This is Argelander Z. 218. No. 85. (c) The counting was found to be 1^s in advance. (d) All the wires have been diminished 1^s. (e) Wire VI has been diminished 1^s. (f) Corrected by +1^s, the counting being 1^s slow. (g) The counting was 1^s in advance of the clock: correction applied accordingly. (h) 'A fainter followed.' (i) 'The second of three of equal magnitude.' (j) The other star is H. C. 37202. (k) Unsteady. (l) Faint from a thick fog. (m) Extremely faint. (n) Counting 1^s slow: correction applied. (o) Dense atmosphere towards the South. (p) 'One nearly equal precedes.' (q) Thick cloud.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',362, -26',877, -13',616, +0',065, +13',537, +26',890, +40',362.

(a) Confused observation, coming too close after the preceding. The counting was thought to be 10" slow, but as the observer was uncertain of the amount, 40" have been added from a comparison with the Ephemeris. (b) Sky just clear. (c) Too faint. (d) Cloudy. (e) Extremely unsteady. (f) Excessively faint. An object of Mag. 12 followed about 12". (g) Deficient illumination of the field. (h) This is Argelander Z. 227 No 611. (i) Observed hurriedly at the first wires. (k) Argelander Z. 223 No 104. (l) Too faint to be seen before; doubtful observation. (m) No other star could be seen. (n) Difficult to observe; so faint. (o) An equal star of nearly the same N.P.D. followed about 11", viz. B.A.C. 6727.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',362, -26',877, -13',616, +0',065, +13',537, +26',890, +40',362, except on Aug. 24, on which day the Illumination was East, and the Equatorial Intervals were -40',362, -26',890, -13',537, -0',065, +13',616, +26',877, +40',362.

(a) Large stars this night were badly defined and moved irregularly. (b) Cloudy. (c) Very faint. (d) Too cloudy for any but bright stars. (e) Dense cloud. (f) Just visible. (g) Considered a good observation. (h) Almost too faint: not seen at the other wires. (i) Hid by clouds at the other wires. (k) 'Preceded by an equal star of greater N.P.D.' (l) Wire VII, which was set down 8,5, has been altered conjecturally. (m) Quite uncertain, noise preventing the heat of the clock from being heard. (n) 'Good.' (o) Disturbance by a carriage passing. (p) The observer thought the counting was 1' slow. No alteration has been made. (q) 'The second of three.' (r) Seen faintly at intervals.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, $-40^{\circ}362$, $-26^{\circ}877$, $-13^{\circ}616$, $+0^{\circ}065$, $+13^{\circ}537$, $+26^{\circ}890$, $+40^{\circ}362$.

(a) Very steady. (b) The counting being 1st slow, all the wires except I and II have been increased 1st. (c) 'A bright star of less N.P.D. preceded about 23rd.' (d) 'Of Mag. 7, accompanied by a north-following star of Mag. 9.' The noted times were 10th in excess. (e) 'One of Mag. 10 and less N.P.D. follows about 11th.' (f) All the wires except the first have been diminished 10th. 'A smaller star of greater N.P.D. follows about 14th.' (g) 'Preceded by one of equal Mag.' (h) Cloudy. (i) Irregular motion and bad definition. (k) Flaring. (l) 'A fainter preceded.' Wires VI and VII have been corrected by -4° . (m) Very bad definition.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, -40',362, -26',877, -13',616, +0',065, +13',537, +26',890, +40',362.

(a) 'A bright star following.' (b) Would scarcely bear sufficient illumination. (c) Stars this night were greatly diffused, and frequently became invisible though no cloud was to be seen. (d) Clouds in the South. (e) The N.P.D. is uncertain. (f) Cloudy. (g) The noted times were 1^h in excess. (h) 'Good.' No object near this. (i) Hid by clouds at wires I and II. (k) Interruption by clouds. (l) Corrected by -1^h. (m) The noted times have been increased by 1^h. (n) Wire III doubtful, the rest satisfactory.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, $-40^{\circ}362$, $-26^{\circ}877$, $-13^{\circ}616$, $+0^{\circ}065$, $+13^{\circ}537$, $+26^{\circ}890$, $+40^{\circ}362$.

(a) Observed hurriedly. Wire V has been increased by 1^s, the seconds being marked doubtful in the memorandum book. (b) Bad definition. (c) The counting for wire II was found to be 5^s in defect: correction applied accordingly. Wire VII was doubtful on account of cloud. (d) Sometimes scarcely visible, at other times flaring. (e) Wires V, VI, and VII have each been decreased 1^s. (f) Considered good. (g) The observations marked with the italic C were taken by R. C. Carrington, Esq. The clock errors by C are put in brackets, being used for determining the difference of the personal equations of B and C. (h) Cloudy at the other wires. (i) The apparent R.A. by C's observations are corrected by $-0^{\circ}30$ for difference of personal equation between B and C. (See Introduction). (k) Extremely faint from cloud. (l) Too much clouded to be observed with any certainty. 'A brighter of less N.P.D. preceded.' (m) 'A brighter of greater N.P.D. followed.'

(a) The correction -0.30 has been applied to C 's apparent R.A. for difference of personal equations of B and C . (b) Very faint. (c) The times by B have been increased 20^s . (d) 'Preceding 60 Aquarii and of less N.P.D.' (e) 'Two preceded, one of greater and the other of less N.P.D.' (f) Extremely faint. The intervals are discordant. (g) Pretty steady during the whole time; wire II not satisfactory. (h) Another of the 9th Mag. and of less N.P.D. preceded about 30^s . (i) 'The only star visible in the field.' (k) Disturbance by noise, and the star very faint. Wire VII appears to be 1^s in defect. 'One of the same Mag. and greater N.P.D. followed 30^s .' (l) The south-preceding of two equal: very faint. The intervals are very irregular: wires II and IV have each been increased 1^s conjecturally. (m) The north-preceding of a coarsely double star. (n) High wind and clouds all the evening.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, -40',362, -26',877, -13',616, +0',065, +13',537, +26',890, +40',362.

(a) One of Mag. 8 and following 10^h, was noticed much lower in the field. (b) A star of Mag. 7 and greater N.P.D. follows. (c) Cloudy.
 (d) A star of Mag. 7,8 was much lower in the field. (e) Taken hurriedly: the shutters not fully open. (f) Correction -0',33 applied to C's apparent R.A. for difference of personal equation of B and C. (See Introduction). (g) Flaring. (h) Two objects of the same R.A. followed. (i) Taken by mere guess, so very faint. (k) Very faint from haze. (l) Hazy. (m) Irregular intervals. (n) Invisible at times. A star somewhat brighter follows. (o) Faint at times. (p) Scarcely visible.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, - 40°, 362, - 26°, 877, - 13°, 616, + 0°, 065, + 13°, 537, + 26°, 890, + 40°, 362.

(a) Correction - 0,33 applied to C's Apparent R.A. for difference of personal equations of B and C. (b) 'Appeared to advance unequally.' (c) Wire IV has been increased 1". (d) Faint. (e) Difficult to observe, so very faint. (f) Too faint to be well observed. (g) Taken doubtfully. (h) Wires VI and VII were too discordant. (i) Flaring. (k) Much diffused. (l) Cloudy. (m) Wire I lost, and wire III uncertain, from clouds. Wire V, set down 53,6, has been rejected. (n) Vanishing at times. 'The south-following of two.' The other is B.A.C. 7202. (o) Advancing unequally. (p) Steady. (q) Considered by C to be of 3rd or 4th Mag.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.	Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, -40',362, -26',877, -13',616, +0',065, +13',537, +26',890, +40',362.

(a) Correction -0',33 applied to C's Apparent R.A. for difference of personal equations of B and C. (b) Cloudy. (c) Very faint at times.
 (d) Very faint. (e) Clouds passing. (f) Flaring. Misty cloud constantly passing. (g) 'The brightest in the field.' (h) Very faint; dense cloud passing. (i) 'Pretty good.' Some of the intervals are discordant: wire IV, which was set down 6^m. 21^s. 5, has been decreased 1^m. (k) Faint.
 (l) The sky being very clear, the Planet could be satisfactorily observed though between the 10th and 11th Mag. No object near this. (m) 'The following and somewhat brighter of two.' Wire IV was written down 46,7.

RIGHT ASCENSIONS OBSERVED WITH THE TRANSIT IN THE YEAR 1849.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, - 40°,362, - 26°,877, - 13°,616, + 0°,065, + 13°,537, + 26°,890 + 40°,362.

(a) Tremulous. (b) Excessively faint, being clouded. Wires III and V have each been increased 2° from a consideration of the intervals. Perhaps, however, the discordance is due to the faintness of the object. (c) Very faint from cloud: bad night. (d) Cloudy. (e) Great motion. (f) The stars were badly defined this night. (g) Invisible at times from motion. (h) 'One of less N.P.D. follows.' (i) This appears to be Argelander Z. 255. N° 21. (k) Extremely faint. 'Another object of the same Mag. and less N.P.D. followed about 12°.' (l) Strong moonlight. (m) 'The brightest of four nearly equal.' (n) 'Of Mag. 9,10: easily observed.' Irregular intervals.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, $-40^s,362$, $-26^s,877$, $-13^s,616$, $+0^s,065$, $+13^s,537$, $+26^s,890$, $+40^s,362$.

(a) Much clouded at the last wire. (b) Cloudy. (c) 'The only object seen.' (d) 'The following of two.' Wire II was written down 14,7.
 (e) Extremely faint. (f) The counting was 1^s in advance on looking at the clock. The noted times have not been altered. 'This star is the last and most southern of several of equal magnitude.' (g) Clouds. (h) Flaring. Wire II, which was written down 33,2, has been altered conjecturally. (i) Dense fog and cloud. (k) 'A fainter of somewhat greater N.P.D. preceded about 10^s.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, -40°,362, -26°,877, -13°,616, +0°,065, +13°,537, +26°,890, +40°,362.

(a) All the wires, except wire I, have been increased 10". (b) Wire VII has been corrected by -1", the counting being 1" in advance. (c) Counting 1" fast; correction applied. (d) Temp. 26°. (e) Misty sky. (f) A faint star preceded. (g) The sky overcast, and the star scarcely visible. Wires I and II very doubtful. (h) Temp. 33°. (i) Extremely faint. (k) The last four wires have been increased 20". (l) The Temperature on the night of Dec. 4 was at 30°.

ILLUMINATION WEST. INTERVALS for an Equatorial star of wires I, II, III, IV, V, VI, VII, from the mean of the seven wires, $-40^s,362$, $-26^s,877$, $-13^s,616$, $+0^s,065$, $+13^s,537$, $+26^s,890$, $+40^s,362$.

(a) Correction -1^s applied, the counting being 1^s in advance of the clock. (b) 'Two stars of less N.P.D. followed.' (c) Corrected by -1^s .
 (d) The lamp was nearly out, and the wires were seen with great difficulty. (e) Very foggy, and great deposition of moisture. (f) Planet faint, but observed satisfactorily. (g) Extremely faint: observed with the utmost difficulty. (h) The difference of the personal equations of II and T given by this observation is $0^s,22$. (i) The sky had cleared shortly before. Between Dec. 19 and Dec. 28 the clock had been cleaned, and its rate was not yet adjusted.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) This Zenith Point was obtained Dec. 20, 1848. (b) Unsatisfactory. The glasses of the eye-piece were foul. (c) 'Good bisection.' (d) Negative correction for Runs. (e) Faint. (f) 'Very faint: not good.' (g) 'Good.' (h) The circle reading has been diminished by 5'. (i) Cloudy. (k) The micrometer reading for another object of equal magnitude 15" distant, was 10",000. The sky had recently become clear. (l) Bad night for observing, the stars being much diffused. Too high wind for Reflection observations. (m) 'Unsatisfactory.' (n) A rich field. A faint star south-preceding, and two of the 9th Mag. north-following. (o) Faint and diffused. (p) Too much day-light for a star of 10th Mag.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°.47'.8",00.

(a) Negative correction for Runs. (b) Uncertain observation on account of the faintness of the star, which was considered to be of 11th Mag. (c) Very faint: of 10th Mag. (d) The south-preceding of two. Uncertain observation, the star being very faint. (e) 'Good observation.' (f) A star of the same Mag. and N.P.D. followed about 30". (g) Apparently an error in the N.P.D. of 1' in defect. (h) Too faint. (i) Taken hurriedly, the Planet not being seen before on account of moisture on the eye-glass. The Circle reading was less by 10". (k) 'The south-preceding of two.' (l) The following star. (m) Several in the field. (n) Clouds had cleared off. (o) Very faint. (p) 'The southern of two of equal magnitude.' They were excessively faint, and the bisections were doubtful. (q) 'The southern of two.' (r) 'Of 9,10 Mag. and getting rapidly fainter: good observation.'

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) A great number of stars in the field: this of 7,8 Mag. (b) The first and most southern of three equal stars in a straight line. (c) Negative correction for Runs. (d) 'Good: no object near this.' (e) Much too faint for certain observation, would have no illumination. (f) 'A fainter of greater N.P.D. precedes.' (g) Excessively faint. (h) 'Unsatisfactory.' (i) 'Of the last degree of faintness.' The clouds cleared off shortly before this observation, but objects appeared faint and diffused from the prevalence of vapour. (k) Indefinite. (l) Extremely faint. (m) The reading of microscope A has been diminished by 1". (n) Both too faint to observe with certainty. (o) Very unsteady. (p) Just visible occasionally: too faint for accurate bisection. (q) A somewhat brighter object of less N.P.D. by 50" preceded about 1 1/2".

ONE REVOLUTION of the MICROMETER = 20".862. ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8".00.

(a) Doubtful observation: the shutters could not be fully opened and the star was faint.
 (b) 'Mag. 7: no object near this.'
 (c) 'Mag. 9: no star near.'
 (d) Negative Correction for Run.
 (e) 'Mag. 10: too faint for certainty. An object of the same mag. and greater N.P.D. follows about 2'.
 (f) 'Mag. 7.8.'
 (g) 'Good: the Planet bright.'
 (h) Too faint to bear illumination. No object was seen near this.
 (i) Too faint for accuracy.
 (j) The R.A. was deduced from a Transit observation taken at two wires.
 (k) 'Mag. 11.12.' The observation was considered good.
 (l) 'The southern of two.'
 (m) Very faint.
 (n) The R.A. is approximate.
 (o) This is Bessel Z. 348, 6^h. 51^m. 46^s.
 (p) This appears to be the south following object noticed Feb. 22.
 (q) Scarcely visible from cloud. No other object in the field.
 (r) Excessively faint. 'The southern of two.'

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) 'The object faint, but the observation, I think, is good.' Probably this is not the Planet. (b) 'The southern of two.' (c) Negative correction for Runs.
 (d) 'The northern of two.' (e) 'Not good.' (f) Too faint for satisfactory observation. (g) The shutter not well open. (h) 'Good.'
 (i) Observed hurriedly. (k) Two very faint objects north-preceding. (l) This night's observations unsatisfactory: the sky had recently become clear after a heavy snow-storm, and stars were extremely unsteady and badly defined. (m) Misty sky and small stars very faint. (n) Extremely difficult to bisect. A fainter preceded. (o) Unsteady.

ONE REVOLUTION of the MICROMETER = $20''862$. ONE INTERVAL from the middle wire for an Equatorial Star = $16''.6$.
 ASSUMED Co-LATITUDE = $37^\circ.47'.8'',00$.

(a) Faint on account of clouds. (b) From April 3 to June 14 the Circle was chiefly employed in taking the Circle Transits of Zodiacal Stars recorded in a subsequent part of the volume. (c) Bisected by T. (d) Negative correction for Runs. (e) After the observations of April 7, the Telescope accidentally struck against the observer's chair. (f) Cloudy. (g) No star near this. (h) Observed satisfactorily. (i) Of the last degree of faintness, disappearing immediately after the bisection. (k) Excessively faint from cloud. (l) Microscopes B, C, D and E were inadvertently read on the negative side of zero: the estimated correction of the Runs for the six readings = $+1''.0$. (m) Faint from cloud.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Uncertain, the mercury being disturbed by wind. (b) Extremely faint. (c) Had definition. (d) 'The preceding of two.' (e) 'The following and brighter.' (f) 'Extremely faint: Mag. 10.' (g) Very faint: could not be seen earlier. (h) Negative correction for Runs. (i) The mercury unsteady. (k) Too faint for accuracy. (l) Doubtful observation, the star being very faint. (m) Numerous stars: this is of Mag. 8, and is preceded by a fainter.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) The Moon near. (b) Extremely faint from cloud. (c) Cloudy. (d) Negative correction for Runs. (e) Taken hurriedly. This object was of Mag. 11, and is probably the same as that observed with the Transit. (f) Observed by mistake for H. C. 33513. (g) 'Another preceded about 10°.' (h) A brighter of less N.P.D. was noticed. (i) Barely visible. (k) Not observed satisfactorily. (l) 'The only star in the field.' (m) 'Coarsely double: the south-preceding taken.' (n) Pretty bright. A very faint object, for which the micrometer reading was 8",348, followed about 20". (o) 'Another of less N.P.D. followed.' (p) 'The brightest of several.' (q) This is Argelander Z. 223, No. 98.

ONE REVOLUTION of the MICROMETER = 20",862.

ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.

ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) 'One of greater N.P.D. preceded 20'. (b) Cloudy. (c) Negative correction for Runs. (d) Could not be seen sooner on account of cloud.
 Another object of greater N.P.D. followed 20'. (e) Very faint. (f) The brightest of several. (g) Faint. (h) 'The south-preceding of two
 stars of Mag. 8.' (i) This is Argelander Z. 239. No. 62. (k) Another object followed about 10', for which the Micrometer reading was 13',144. (l) The
 observations marked with the Italic C were taken by R. C. Carrington, Esq. (m) 'Very good.' (n) Satisfactory observation.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) 'Many stars in the field.' This is Argelander Z. 244, No. 33. (b) Argelander Z. 240, No. 81. (c) Extremely faint, but considered to be well bisected. (d) Negative correction for Runs. (e) Very faint. (f) Rain all the evening. (g) The negative divisions were inadvertently bisected with microscopes D, E, and F. Total correction for Runs of the six microscopes = +0",3. The observer was doubtful whether the circle was clamped. (h) Faint from clouds. (i) 'Not good.' (k) The readings of microscopes D and F were 48,5 and 50,3. They have been altered conjecturally. (l) 'A bright star preceded.' (m) Excessively faint, but the observation not altogether doubtful. (n) As good an observation as the faintness of the object allowed of.

ONE REVOLUTION of the MICROMETER = 20",862.
 ASSUMED CO-LATITUDE = 37°.47'.8",00.

ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.

(a) Very faint, but the observation not doubtful. (b) Negative correction for Runs. (c) 'Good.' (d) Very faint. (e) The recorded circle reading was 1" greater. (f) Seen only at intervals. (g) By a circle transit of α Aquarii Oct. 10 Molyneux was fast 2^m. 27^s. Mercury unsteady. (h) Another of equal Mag., of the same R.A. and less N.P.D. (i) Cloudy. (k) Doubtful bisection, the star being barely visible through cloud. (l) Much obscured by cloud.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5".	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refract.	Apparent N.P.D. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8".00.

(a) 'The north-preceding and brighter of a coarsely double star.' (b) 'South-following the double star.' (c) 'A smaller of less N.P.D. precedes.'
 (d) Negative correction for Runs. (e) Cloudy. (f) 'An object of equal magnitude preceded at some distance.' (g) 'A bright star of less N.P.D. preceded.'
 (h) 'A close double star, followed by a faint star of greater N.P.D.' (i) 'A fainter object followed about 13'.' (k) Too faint for accurate bisection. 'The south-preceding of two of nearly equal magnitude.' (l) 'Pretty good; no object near.' (m) 'Preceding the next star about 16'.'
 (n) A diffused mass of light was bisected, the mercury being much disturbed. (o) The Planet bright and observed with certainty.

(a) Very faint, but the observation was not doubtful. No other object was seen. (b) Negative correction for Runs. (c) Extremely faint, but admitting of bisection. (d) 'The north-preceding and brighter.' (e) 'The south following.' (f) 'Good.' (g) 'The preceding of two equal and of the same N.P.D.' The other is Bessel xxiii. 897. (h) 'Alone.' (i) Very faint. (k) The mercury too much disturbed for the reflection observation. (l) Faint, but observed satisfactorily. (m) Faint from cloud. (n) 'The north-following of two.' The other is Bessel xxii. 747. (o) Very faint from haze. (p) Unsteady.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°.47'.8",00.

(a) Unsteady. (b) Negative correction for Runs. (c) The sky was covered with dense haze. (d) Disappearing at intervals. (e) Very faint from haze. (f) 'Good.' (g) Very faint from cloud. (h) Mist. (i) Faint. (k) 'Bisection doubtful.' (l) Extremely faint from mist and cloud. (m) 'Doubtful observation.' (n) Haze. (o) Deposition of moisture on the glasses of the microscopes made the circle divisions almost invisible. (p) Doubtful bisection on account of the faintness of the object and moisture on the eye-glass. (q) Very faint. (r) The microscopes dripping with moisture. (s) Very faint, the observer not being able to free the eye-piece from moisture.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Diffused. (b) Continuous cloudy weather from Dec. 8 to Dec. 17. (c) Extremely faint and difficult to bisect. (d) Strong wind.
 (e) Negative correction for Runs. (f) Became visible just before passing the 4th wire: no other object was seen. (g) The direct observation was prevented by a board in the way, which happened at the time to cross the shutter opening. (h) The reading of Microscope D appears discordant: it should probably be 18",9.

MEAN NORTH POLAR DISTANCES OF THE STARS

OBSERVED IN THE YEAR 1849,

AS DEDUCED FROM EACH DAY'S OBSERVATION,

WITH

THE CORRECTIONS APPLIED TO

THE APPARENT NORTH POLAR DISTANCES.

CATALOGUE
OF THE
CONCLUDED MEAN RIGHT ASCENSIONS
AND THE
CONCLUDED MEAN NORTH POLAR DISTANCES,
JANUARY 1, 1849,
OF THE STARS OBSERVED IN THE YEAR 1849;
WITH THE ANNUAL VARIATIONS.

CATALOGUE of the CONCLUDED MEAN RIGHT ASCENSIONS AND MEAN NORTH POLAR DISTANCES,
JAN. 1, 1849; with the ANNUAL VARIATIONS.

** The N.P.D. have been corrected for the Discordance of Zenith Points, and the Error of the Assumed
Co-latitude, in the manner explained in the Introduction.

Reference Number.	Name of Star.	Observed Magnitude.	Number of Obs. of R.A.	Concluded Mean R.A., or, Approximate Mean R.A., Jan. 1, 1849.	Annual Variation in R.A.	Number of Obs. of N.P.D.	Concluded Mean N.P.D., or, Approximate Mean N.P.D., Jan. 1, 1849.	Annual Variation in N.P.D.	Notes.

No. 285. This is H. C. 26050, the R.A. of which is 28^h 39^m too great, being reduced as if the observation were taken at the middle wire.

No. 291. This star was noted to be "extremely faint." By Bessel the magnitude is 8, and the N.P.D. 8'' greater. The identity is doubtful.

No. 303. The magnitude was estimated in too much day-light.

APPROXIMATE
RIGHT ASCENSIONS AND NORTH POLAR DISTANCES
OF
ZODIACAL STARS
OBSERVED WITH
THE MURAL CIRCLE,
IN THE YEAR 1849.

Month and Day.	NAME OF STAR.	Seconds of transit over the five wires.					Concluded transit over the mean of the five wires.	Correction of transit-time for known star.		Adopted gaining rate of clock.	Correction for 1 st of increase of R.A.	Correction for 1 st of increase of N.P.D.	Correction of transit-time for unknown stars.		Apparent R.A. from the Observation.	Observer.

INTERVALS for an Equatorial Star of wires I, II, III, IV, V, from the mean of the five wires, - 32°, 824, - 16°, 441, - 0°, 089, + 16°, 468, + 32°, 886.

(a) Mercury tremulous at wire V. (b) Good. (c) Cloudy. (d) Very windy: mercury unsteady. (e) Very faint. (f) Blazing.
 (g) Probably 1st in defect: not used for reduction to the meridian. (h) Wires I and II good. (i) Corrected by 0,33 for difference of personal equation of C and B.
 (k) Not good: the mercury tremulous and a dense fog.

Month and Day.	NAME OF STAR.	Seconds of transit over the five wires.					Concluded transit over the mean of the five wires.	Correction of transit-time for known stars.		Adopted gaining rate of clock.	Correction for 1 ^h of increase of R.A.	Correction for 1 ^h of increase of N.P.D.	Correction of transit-time for unknown stars.		Apparent R.A. from the Observation.			Observer.

INTERVALS for an Equatorial Star of wires I, II, III, IV, V, from the mean of the five wires, - 32', 824, - 16', 441, - 0', 089, + 16', 468, + 32', 886.

(a) Well defined. (b) One of equal magnitude precedes. (c) Thick cloud passing. (d) The observer was disturbed. (e) Cloudy.
 (f) The observed time has been diminished 1^m. The star is H. C. 23815, the minutes of the R.A. of which are the same as Bessel's. (g) Very faint.
 (h) Good. (i) Clouds passing. (k) Faint at times from cloud. (l) Sometimes quite obscured. (m) Clouds passing; the last wire good.

Month and Day.	NAME OF STAR.	Seconds of transit over the five wires.					Concluded transit over the mean of the five wires. h. m. s.	Correction of transit-time for known star. m. s.	Adopted gaining rate of clock. s.	Correction for 1 ^h of increase of R.A. s.	Correction for 1 ^h of increase of N.P.D. s.	Correction of transit-time for unknown stars. m. s.	Apparent R.A. from the Observation. h. m. s.	Observer.

INTERVALS for an Equatorial Star of wires I, II, III, IV, V, from the mean of the five wires, $-32^{\circ}.824$, $-16^{\circ}.441$, $-0^{\circ}.089$, $+16^{\circ}.468$, $+32^{\circ}.886$.

(a) Misty. (b) Near the Moon. (c) A brighter of greater N.P.D. preceded. (d) Not good; observed hurriedly. (e) The Moon near. (f) Wire II is perhaps 1s too little. (g) The south-following and brighter of two. (h) Wire V was set down 11.7. (i) Very irregular intervals: the observer was much disturbed. (k) No definition. (l) Much tremor: wire III not good. (m) Faint. (n) The counting was 11s in advance: correction applied accordingly.

Month and Day.	NAME OF STAR.	Seconds of transit over the five wires.					Concluded transit over the mean of the five wires.	Correction of transit-time for known star.		Adopted gaining rate of clock.	Correction for 1 ^h of increase of R.A.	Correction for 1 ^o of increase of N.P.D.	Correction of transit-time for unknown stars.		Apparent R.A. from the Observation.	Observer.

INTERVALS for an Equatorial Star of wires I, II, III, IV, V, from the mean of the five wires, - 32', 824, - 16', 441, - 0', 089, + 16', 468, + 32', 886.

(a) Faint from cloud. (b) The counting was 1^s in advance of the clock. (c) Corrected by + 1^s for erroneous counting. The star was very faint.
 (d) Corrected by + 30^s. (e) Extremely faint. (f) Corrected by - 2^s for error of counting. (g) Not good. (h) The noted times have been increased 1^s conjecturally. (i) The observed time was 1^m greater. The assumed apparent R.A. of this star was deduced from the Greenwich 12-year Catalogue.
 (k) The noted times were 1^s less, giving a discordant clock-error. Either an error of counting was committed in the hurry of observing Spica so shortly after wire IV of Polaris SP, or, as I rather think, the instrument takes time to settle after being moved through large angles.

Month and Day.	NAME OF STAR.	Seconds of transit over the five wires.					Concluded transit over the mean of the five wires.			Correction of transit-time for known star.		Adopt- ed gaining rate of clock.	Correction for 1 ^h of increase of R.A.	Correction for 1 ^h of increase of N.P.D.	Correction of transit-time for unknown stars.		Apparent R.A. from the Observation.			Observer.

INTERVALS for an Equatorial Star of wires I, II, III, IV, V, from the mean of the five wires, $-32^s,824$, $-16^s,441$, $-0^s,089$, $+16^s,468$, $+32^s,886$.

- (a) The observation was thought to be 1st slow: it has been altered accordingly. (b) At wires I and II the star was distant from the middle of the field.
(c) The star was not brought to the middle of the field till after wire III. (d) Discordant intervals. It is supposed that the circle was clamped after wire III.
(e) Perhaps 1st slow. The observer was often interrupted by noise, and could not well keep the count in the earlier part of the evening. (f) Corrected by 1st conjecturally. See the note to Spica May 31. (g) Steady. Wire II has been increased 1st by a consideration of the intervals. (h) Cloudy.
(i) Considered good. (k) The Moon nearly on the meridian and stars consequently faint. (l) The following of two of equal magnitude. (m) Steady.
(n) The observed times were thought to be 1st slow and have been altered accordingly. (o) Interruption by noise. The noted times are probably 1st slow.

Month and Day.	NAME OF STAR.	Seconds of transit over the five wires.					Concluded transit over the mean of the five wires.	Correction of transit-time for known stars.		Adopted gaining rate of clock.	Correction for 1 ^h of increase of R.A.	Correction for 1 ^h of increase of N.P.D.	Correction of transit-time for unknown stars		Apparent R.A. from the Observation.	Observer.

INTERVALS for an Equatorial Star of wires I, II, III, IV, V, from the mean of the five wires, $-32^s,824$, $-16^s,441$, $-0^s,089$, $+16^s,468$, $+32^s,886$.

(a) Indefinite. (b) Extremely faint. (c) Confused at first. (d) The noted times were thought to be 1^s slow and have been altered accordingly. (e) The observation was thought to be 1^s in error: no alteration has been made. (f) A star of equal magnitude preceded. (g) All the wires except the first have been increased 1^s. During this and preceding observations the observer was much disturbed by noises. (h) Too faint for a satisfactory observation. (i) This observation of Spica, being unaccompanied by one of Polaris SP., presents no discordance in the clock-error. (k) Corrected by -1^s for error in counting. (l) Very faint. (m) Doubtful on account of the faintness of the object. (n) Clouds. (o) Unsteady.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°.47'.8",00.

(a) Cloudy.

(b) Negative correction for Runs.

(c) This is H. C. 20301.

(d) Unsatisfactory bisection.

(e) The south star.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.
 ASSUMED CO-LATITUDE = 37°.47'.8",00.

(a) Negative correction for Runs. (b) The N.P.D. by this observation exceeded by 10' that of B.A.C. and of the observations on June 13, and has been altered accordingly. (c) The instrument having been accidentally unclamped before reading off Microscope B, the reading for this Microscope is supplied conjecturally from the following observation and the two preceding. (d) Cloudy. (e) Extremely faint. (f) Bisection doubtful.

ONE REVOLUTION of the MICROMETER = 20",862. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Negative correction for Runs. (b) Extremely faint. (c) Too faint for satisfactory bisection. (d) Bisection doubtful. (e) Very faint.
 (f) The middle star of three. (g) The R.A. may be in error a few seconds. (h) Eye-piece misty. (i) Correction for Run of A = 0",0, being negative;
 for that of B = + 4",6. (k) Extremely faint from cloud.

Nº. 7. The R.A. is about 1^s.75 greater than that of H. C. 19229, and the N.P.D. about 40'' greater than the N.P.D. of the same star.

Nº. 21. The R.A. by the observation has been decreased 1^m, Bessel's being supposed to be correct.

Nº. 31. The observed N.P.D. is 1' less than Bessel's, but agrees with that of H. C. 20304.

Nº. 58. The R.A. is about 1^s.6 less than Bessel's, which is 1^s greater than that of H. C. 20883.

Reference Number.	Name of Star.	Observed Magnitude.	Day of Observation of R.A.	Correction to Mean R.A. Jan. 1, 1849.	Concluded Mean R.A., or, Approximate R.A., Jan. 1, 1849.	Annual Variation in R.A. N°. 68. The R.A. is about 10° greater than Bessel's and that of H. C. 21032, and is most probably erroneous to that amount.

N°. 98. The N.P.D. is 1' greater than Bessel's.

N°. 104. The R.A. agrees with Bessel's: the precession in Weiss's Catalogue should be 3".128.

No. 125. The estimation of magnitude was probably affected by the Moon being near.

No. 128. The N.P.D. agrees with that of H. C. 21809: Bessel's is 1' less.

No. 156. The R.A. is 10° greater than that of H. C. 22180, which is erroneously reduced.

No. 163. The N.P.D. is about 16" greater than that of B.A.C., but agrees with the N.P.D. of Bessel xi. 722.

No. 168. The N.P.D. is 15" greater than that of H. C.

Nº. 260. Bessel's R.A. is about 1^s.7 greater.

Nº. 264. Bessel xiii. 131 is of greater R.A. by 12^s, agreeing well enough in N.P.D. Two stars were not noticed.

Nº. 265. Agrees in R.A. with Bessel xiii. 128, but has less N.P.D. by about 2½'.

Nº. 290. The same star as H. C. 25378, supposing an error of 1° in excess in the N.P.D. of H. C.

Nº. 384. The magnitude was estimated doubtfully.

Nº. 402. The N.P.D. agrees with that of H. C.: the N.P.D. of Bessel xv. 666 is 10' greater.

Nº. 426. The R.A. of H. C. is 3° less.

RIGHT ASCENSIONS

Aug. 13, Oct. 9, Oct. 13, and Nov. 21. At only two wires.

Aug. 16. See the Transit observation.

Nov. 13. See the Transit observation: wire IV probably should not have been altered.

The observations were generally uncertain, the Planet being low and too faint for bisection with fine wires in an illuminated field.

OCCULTATIONS
OF
FIXED STARS BY THE MOON,
WITH
THE EQUATIONS GIVEN BY THE CALCULATION
OF THE OCCULTATIONS.

1849.

COMPARISONS OF CLOCKS AND CHRONOMETERS USED IN THE CALCULATION
OF THE FOLLOWING OCCULTATIONS.

* * THE letter *H* is an abbreviation for Hardy, the Transit Clock; *G* for Graham, the Clock commonly used with the Five-feet Equatorial. *U* and *X* are Sidereal Chronometers, and *W* is a Solar Chronometer, each beating half-seconds.

			X.	Northumb. Equat.	0.19.21,7	0.19.49,74	7.45.9,65	B.

(a) 'The star disappeared instantaneously: no doubt of the time to the tenth of a second.'

(b) The occultation was watched for ten minutes, but the instant of disappearance was altogether uncertain, the star becoming very faint as it approached the Limb. 'The Moon was of a copper-colour and had a boiling motion.'

(c) Both observations considered to be very good.

(d) 'Very exact.'

(e) This occultation, which is not in the Nautical Almanac, took place near the South Limb during an eclipse of the Moon. The star was noted of Mag. 6, and found to be 82 Leonis. The instrument was not mentioned, but most probably it was the 5-feet Equatorial, the Northumberland Telescope being on the point of being used for observations of Flora. The observation was considered good.

(f) Probably observed too late, the 'Angle from Vertex' not according with that of the Nautical Almanac.

(g) Clouds passing made it doubtful whether the star was hid by the Moon at the time noted.

(h) Probably a few seconds late, the right point of the Limb not being looked at.

(i) 'Not a second late, the Moon's Limb being well defined and the right position looked at.'

(k) Doubtful to a few seconds, the Moon's Limb waving and the star being a very faint patch of light.

(l) The Moon nearly full and the star faint, but the observation was not doubtful.

(m) Considered exact. The seconds were counted by T.

(n) No uncertainty.

(o) Circumstances not noted.

(p) Star faint, but the observation not doubtful.

(q) 'The star appeared to dance on the Limb for two seconds.'

(r) Uncertain, the star being very faint.

(s) The observer had removed his eye from the Telescope for about two seconds and the time may therefore be in error to that amount.

(t) 'Star extremely faint: it appeared to rest on the Limb a few seconds.' (T). 'The Moon full, and misty clouds passing. Very exact observation, the star being kept in view till it appeared to touch the Limb.' (B).

In calculating the Greenwich Mean times of Sept. 8, the change of error of W in the interval between the observation and the comparisons is allowed for when necessary, its rate being inferred from the first and last comparisons of that day.

Disappearance of ξ^1 Ceti, Jan. 3, $5^h.47^m.48^s.39 + t^s + \tau^s$ Greenwich Mean Solar Time.

Right Ascension of Zenith in arc	$10^{\circ}.16'.35''.10 + 15''.0411 \times t$
Moon's Geocentric Right Ascension in arc	$30.55.55.20 + 0,5745 \times (t + \tau) + x''$
Moon's Geocentric N.P.D.	$81.25.27.88 - 0,1691 \times (t + \tau) + y$
Moon's Horizontal Parallax at the Observatory	$59.21.86 \times [9,9990916] \times (1 + 0,001 m)$
Moon's Geocentric Semidiameter.....	$16.10.61 \times (1 + 0,001 n)$
Star's Right Ascension in arc.....	$31.15.7.50 + e''$
Star's N.P.D.	$81.51.57.30 + f$
Geocentric Colatitude of the Observatory	$37.58.20.37 + v$
Moon's apparent Right Ascension in arc.....	$31^{\circ}.9'.3''.24 + \delta R$
Moon's apparent N.P.D.....	$82.7.2.87 + \delta \lambda$
Moon's apparent Semidiameter.....	$16.22.16 + \delta S$
Apparent Distance of Star from Moon's centre	$16.14.76 + \delta D$

$$\delta R = +0,4279t + 0,5804\tau + 1,0101x - 0,0006y + 0,7960m + 0,0049v$$

$$\delta \lambda = -0,1787t - 0,1708\tau + 0,0005x + 1,0118y + 2,5249m - 0,0124v$$

$$\delta S = +0,0003t + 0,9822n$$

$$\delta D = -0,3664\delta R + 0,3664e + 0,9291\delta \lambda - 0,9290f.$$

Final Equation:

$$+7''.40 = -0,3697x + 0,9403y + 0,3664e - 0,9290f - 0,3231t - 0,3714\tau - 0,0133v + 2,0540m - 0,9822n.$$

Disappearance of 38 Virginis, Jan. 14, $12^h.6^m.41^s.62 + t^s + \tau^s$ Greenwich Mean Solar Time.

Right Ascension of Zenith in arc	$116^{\circ}.5'.58''.80 + 15''.0411 \times t$

ILLUMINATION WEST. From Jan. 13, ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,337, -26°,913, -13°,618, +0°,060, +13°,573, +26°,892, +40°,344. From Jan. 13, -46°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337.

(a) Scarcely visible from clouds. (b) The N.P.D. may not be exact to a minute. (c) Cloudy. (d) Corrected by -1°, the counting being found 1° in advance. (e) Unsteady. This observation at only two wires was inadvertently used in the calculation of clock-error. (f) Before this observation Hardy was stopped to diminish the rate. (g) Jan. 15, 0^h, Hardy was again stopped to give it a losing rate. (h) Almost hid by clouds.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.
		I	II	III	IV	V	VI	VII		Collimation Error.	Level Error.	Azimuth Error.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337.

(a) No clock-stars could be observed this day. (b) Disturbance. (c) Faint. The noted times were 4^s less. (d) Cloudy nearly all this evening.
 (e) Clouds passing. (f) The N.P.D. is not exact. 'Two stars of magnitudes 5½ and 7 follow this.' (g) 'A brighter of greater N.P.D. precedes this 2^d.'
 (h) Cloudy. (i) Faint. (k) Used for clock-error, α Hydræ being observed at only three wires. (l) The sky overcast. (m) Faint from cloud.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,337, -26°,913, -13°,618, +0°,060, +13°,573, +26°,892, +40°,344.

(a) Very great motion. Wires VI and VII were written down 20,2 and 31,1, and have been altered conjecturally. (b) Cloudy. (c) Without the dark glass. (d) 'Very good.' (e) Faint. (f) The noted times have been diminished by 1". (g) A fainter of somewhat greater N.P.D. precedes about 5". (h) Another of Mag. 8 and less N.P.D., follows 3". (i) The south-preceding star; the other is of Mag. 7. (k) Bad illumination of the field. The noted times have been diminished 15". (l) Observed for H. C. 13673. The N.P.D. is uncertain. (m) Clouded: barely visible at wire II. (n) Hazy. (o) Scarcely visible. (p) All the wires except I and II have been diminished 1". (q) Mist. (r) 'A brighter of Mag. 7.8 and less N.P.D. follows,' viz. H. C. 13315.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,337, -26°,913, -13°,618, +0°,060, +13°,573, +26°,892, +40°,344.

(a) Very faint. (b) The noted times were 13^s greater. (c) Very tremulous. (d) Beautifully defined. (e) Mist. (f) Bad definition.
(g) Very faint at times. The intervals are irregular. (h) One somewhat brighter of the same N.P.D. precedes about 45^s.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s,344$, $-26^s,892$, $-13^s,573$, $-0^s,060$, $+13^s,618$, $+26^s,913$, $+40^s,337$.

March 18, 23^h, Hardy was put forward 1^m.

(a) Bad definition. (b) Corrected by +1^s, the counting being 1^s short. (c) After clouds had cleared off. (d) Loud wind. (e) 'A brighter of less N.P.D. precedes.' (f) The noted time was 1^m greater. (g) The noted times were 1^s less. (h) 'Followed by a smaller of greater N.P.D.' (i) Flaring. (j) Very tremulous and badly defined. No clock-stars could be obtained this day. (l) The evening had been cloudy. (m) 'A fainter of somewhat less N.P.D. precedes about 15^s.' (n) Cloudy. Should the time be 1^m greater? (o) The field not sufficiently illuminated. (p) Doubtful observation.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. From April 5, ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^{\circ}344$, $-26^{\circ}892$, $-13^{\circ}573$, $-0^{\circ}060$, $+13^{\circ}618$, $+26^{\circ}913$, $+40^{\circ}337$. From April 5, $-40^{\circ}337$, $-26^{\circ}913$, $-13^{\circ}618$, $+0^{\circ}060$, $+13^{\circ}573$, $+26^{\circ}892$, $+40^{\circ}344$.

(a) Extremely faint; no object near this. (b) The noted times have been increased by 30". (c) Between March 30 and April 5, observations with the Transit were suspended, the instrument undergoing alterations. (d) The counting was 10" slow. (e) All the wires, except I, have been diminished 10". (f) The counting was 10" fast. The N.P.D. of the star is uncertain. (g) All the wires, except I and II, have been diminished 10". (h) Observed for Hebe, which by mistake was looked for in its place for April 6. (i) Clouds had just cleared off. (k) Faint from cloud. (l) Cloudy: wires VI and VII without the dark glass. (m) Faint. (n) A star of equal magnitude and greater N.P.D. precedes. (o) Correction $-30''$ applied to all the wires except wire I. (p) Correction $+10''$ applied to the five last wires. (q) The noted times were 10" greater, and have been diminished conjecturally.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. From April 15, ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^{\circ}.337$, $-26^{\circ}.913$, $-13^{\circ}.618$, $+0^{\circ}.060$, $+13^{\circ}.573$, $+26^{\circ}.892$, $+40^{\circ}.344$. From April 15, $-40^{\circ}.344$, $-26^{\circ}.892$, $-13^{\circ}.573$, $-0^{\circ}.060$, $+13^{\circ}.618$, $+26^{\circ}.913$, $+40^{\circ}.337$.

(a) 'A star of magnitude 8 and less N.P.D. preceded.' (b) Very faint. (c) Cloud. (d) Doubtful observation, the star being very faint from clouds. Wire I was written down 3.2. (e) 'A star of equal magnitude and the same R.A. was much lower in the field.' (f) 'One of equal magnitude and less N.P.D. followed about 13.' (g) 'A brighter of greater N.P.D. preceded about 8.' (h) Correction $-10''$ applied to all the wires except I. (i) 'No star near this.' (k) Extremely faint. (l) Cloudy.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40",344, - 26",892, - 13",573, - 0",060, + 13",618, + 26",913, + 40",337.

(a) Too faint; could only be seen by glimpses on account of mist and twilight. (b) Observed with difficulty, being very faint. (c) A fainter of the same N.P.D. follows. (d) Cloudy. (e) Seen only at intervals. (f) Extremely faint, but observed satisfactorily. (g) A fainter of less N.P.D. precedes. (h) Bad definition. (i) Scarcely visible. (k) The noted times have been diminished by 8". (l) A star of equal magnitude and greater N.P.D. precedes about 24". (m) A brighter of greater N.P.D. precedes. (n) A fainter of the same R.A. was higher in the field. (o) Followed by a fainter of the same N.P.D. (p) H. C. 23583 was looked for. This is H. C. 23584.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337.

(a) 'The most southern of three of equal magnitude.' (b) Corrected by -1', the counting being 1' fast. (c) Dense mist drifting. 2 L. was not full. (d) Bad definition and irregular motion; dense clouds passing. (e) Tremulous; wire VII doubtful. (f) Bad definition and unsteadiness. (g) Too much motion. (h) Cloudy. (i) Thick cloud; the Moon faint at times. (k) The noted times were 31' greater. Not used for clock-error. (l) No clock-stars could be observed. (m) Waving and difficult to observe. (n) Very faint. (o) Wire IV was set down 20,1 and has been altered conjecturally. (p) The counting was 1' in advance of the clock. 'A brighter of greater N.P.D. precedes' (q) 'The northern and brighter of two.' (r) 'The north-following of two of equal magnitude.' (s) The last four wires have been diminished 30'.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40^s.344, - 26^s.892, - 13^s.573, - 0^s.060, + 13^s.618, + 26^s.913, + 40^s.337.

(a) The observer was doubtful whether it was taken at the 3rd or 4th wire. Too faint to be seen at the other wires. (b) The first limb was clouded. A spot was observed to pass wires IV and V at 2.40.42 and 2.40.18.2. The counting for 2 L. was 1^s short. (c) Clouds had just cleared off. (d) 'The north-following and fainter of two.' (e) Cloudy. (f) The counting was 10^s in advance of the clock. 'A very faint object of the same N.P.D. followed.' (g) Corrected by -2^s for error of counting. (h) Clouded at Wire V. 'The Planet is now of Mag. 9.10.' (i) 'One of equal magnitude and nearly the same N.P.D. preceded.' (k) Corrected by -1^s for error of counting. (l) Corrected by +1^s for error of counting. (m) Observed hurriedly. (n) 'The following of two of equal magnitude 13^s apart.' (o) Good definition. (p) Dense cloud. (q) Flaring. (r) The noted times were 1^s in defect. (s) 'Two spots passed wire V at 3.6.43.5 and 3.6.53.0.'

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40",344, - 26",892, - 13",573, - 0",060, + 13",618, + 26",913, + 40",337.

(a) Badly defined. (b) Not good; disappearing at times. 'There was another object of the same magnitude and nearly the same R.A., and of greater N.P.D. by about 3'. (c) Cloudy. (d) Extremely faint. (e) A mere patch of light. (f) Hid at the other wires. (g) 'Two spots passed wire VII at 3.18.24.3 and 3.18.32.6.' See May 10. (h) Faint from cloud. (i) Cloudy at the last three wires. (j) Blazing. (k) Disturbance. (m) So much noise that the beat of the clock was often inaudible. (n) 'The components have the same R.A.' (o) 'Very good.' (p) 'Extremely faint and at times disappearing.' (q) Great motion. (r) All the wires, except II, have been diminished 30". (s) Corrected by + 11" for error of counting. (t) Cloud. (u) 'Badly defined, but pretty good observation.' (x) Flaring. (y) Corrected by + 19" for error of counting. (z) Faint.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°,344, - 26°,892, - 13°,573, - 0°,060, + 13°,618, + 26°,913, + 40°,337.

(a) Very cloudy. (b) Faint, the shutter intercepting. (c) Cloud. (d) The counting was 1^s short. Extremely high wind. (e) No clock-stars could be observed. (f) Without the dark glass. (g) Very faint. (h) 'A brighter of nearly the same R.A. was higher in the field.' (i) 1 L. hid by cloud. (k) 'A brighter followed higher in the field.' (l) Corrected by - 9^s for error of counting. (m) Very faint: the intervals are irregular. (n) Cloudy. (o) Failure of the pencil.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian transit.	Clock apparently slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40^s,344, - 26^s,892, - 13^s,573, - 0^s,060, + 13^s,618, + 26^s,913, + 40^s,337.

(a) Very bad definition. The evening was cloudy. (b) Very faint. (c) Faint at intervals. (d) Corrected by - 5^s for error of counting. (e) Faint, but the observation was not doubtful. (f) Corrected by + 1^s for error of counting. (g) Not seen to be double. (h) Not too faint for satisfactory observation. Wire IV, which was set down 32,0, has been altered conjecturally. (i) Faint and diffused. (k) Clouded and very faint. (l) Cloudy. (m) 'A fainter of less N.P.D. follows at the distance of two intervals.' (n) 'Another of less N.P.D. distant by 2¹/₂ intervals.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Second of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.	Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',344, -26',892, -13',573, -0',060, +13',618, +26',913, +40',337.

June 16, 21^h, Hardy was put forward 1^m.

(a) Not good. Cloud came over after wire IV. (b) Vibrating. Cloudy at wire II. (c) Pretty steady. (d) Clouded and faint. (e) After wire IV the star became very faint. (f) Without the dark glass, the Lumb being much clouded. Wire IV, which was set down 40,0, is rejected as being discordant. (g) Faint from haze. The evening had been quite cloudy. (h) Haze and cloud. (i) Cloudy. (k) Steady. (l) Faint from cloud. (m) 'The star was low in the field.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°.344, -26°.892, -13°.573, -0°.060, +13°.618, +26°.913, +40°.337.

(a) Bright. (b) Generally without the dark glass. (c) 'A brighter of Mag. 6½ and greater N.P.D. preceded.' The preceding star is Argelander Z. 301, No. 99. (d) Not so bright as on former nights. (e) Cloudy. (f) Corrected by +18 for error of counting. (g) Very faint. (h) No clock-stars could be observed before midnight. (i) 'Two brighter preceded.' (j) Very faint from cloud. (k) Invisible at the other wires. This observation is used for clock-error, a weight of one-third being given to it. (l) Without the dark glass. Wires VI and VII of 21 have been increased 1". (m) Illtherto cloudy. (n) Micrometer intervals from the middle wire, -5', -4', +4', +5'. This and the preceding are reduced as one observation. (p) Much diffused. (q) Beautifully defined.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s,344$, $-26^s,892$, $-13^s,573$, $-0^s,060$, $+13^s,618$, $+26^s,913$, $+40^s,337$.

July 21, 23^h, Hardy was put forward 1^m, and the hour-hand was adjusted.

(a) Clouds and unsteadiness. Micrometer intervals from the middle wire, $-5'$, $-4'$, $-2'$, $+1'$, $+2'$, $+3'$, $+5'$, $+6'$, $+7'$, $+8'$, with an error of 0^s,007 in defect in the coincidence reading used. Hence the correction to the middle wire is $-2^s,107$, or in time $-1^m,32^s,31$, 13^s being by the observation equal to 569^s,5. (b) Clouds. During this observation the Illumination was West, and the Equatorial Interval of wire I from the mean of the wires was $-40^s,337$. The times for 1 L have been increased 23^s. (c) Clouded at the other wires. (d) Mist. The small star seen. (e) Much obscured by cloud. (f) Cloudy. (g) All the wires except I and II have been corrected by -2^s . (h) The last three wires have been increased 10^s. (i) Unsteady. (k) Not seen through the dark glass after wire III and too bright without it. (l) Unsteady and badly defined. The last four wires of 1 L, and the last five wires of 2 L, have been increased 10^s.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40",344, - 26",892, - 13",573, - 0",060, + 13",618, + 26",913, + 40",337.

(a) These two have the weight of one observation, and the apparent R.A. of the clock-stars are consequently not calculated. (b) Cloudy. (c) Unsteady. (d) Well defined. (e) Steady. (f) 'Another of less N.P.D. follows.' The two stars are Argelander Z. 220, N°. 164 and 155. (g) 'Two rather brighter in the south following quarter.' (h) Very faint. (i) Hurried at wire I. (k) This is H. C. 41049. (l) 'The north and brighter of two,' as represented by a diagram. The other is Bessel xxi. 296. 'Another of greater N.P.D. followed,' viz. Bessel xxi. 307. (m) Dense cloud. (n) The sky clear for a short time. (o) All the wires, except I and II, have been increased 10". (p) Flaring. (q) Very unsteady. (r) The first limb lost by the pencil breaking. (s) 'An excessively faint object.' Wires I and IV seem discordant. (t) Seen faintly through cloud.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40^s.344, -26^s.892, -13^s.573, -0^s.060, +13^s.618, +26^s.913, +40^s.337.

(a) Cloud. (b) The borders of a spot near 2 L passed wire II at 9.41.28 and 9.41.29. (c) Wire III doubtful. (d) The reduction to the meridian = +1^s.06 by special calculation. (e) The last four wires have been diminished 10^s. (f) Cloudy before and after this observation. (g) After clearing. (h) 2 L hid by cloud. (i) This observation, taken at only two wires, was inadvertently used for clock-error. (k) Densely clouded. (l) Unsteadiness. (m) Faint. (n) Cloudy at times: some wires of 1 L doubtful. (o) Just after clearing. (p) Not quite full. (q) The counting was found to be 1^s slow: correction applied accordingly. (r) All the wires, except I and II, have been increased 30^s.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337.

Aug. 27, 22^h, Hardy was put forward 1^m.

(a) Cloud. (b) Wires VI and VII taken confusedly. The noted time has been decreased 1^m. 'A smaller or less N.P.D. followed.' (c) Faint. (d) The last three wires have been increased 10^s. (e) 'Too faint.' Observed for H. C. 42238, the N.P.D. of which appears to be erroneous. (f) Dense cloud: partly without the dark glass. The observation of 1 L is retained, the other being taken at only three wires. (g) Extremely faint and unsteady. (h) Great tremor and bad definition. Disturbance at wire V. (i) Very unsteady. (k) Irregular motion. The counting was 1^s slow: correction applied. (l) Good. (m) Very tremulous. (n) Clouds.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',344, -26',892, -13',573, -0',060, +13',618, +26',913, +40',337.

(a) Shortly after this observation the sky suddenly became completely overcast. (b) Limbs waving and ragged. Wire 1 of 2 L. taken hurriedly. (c) Cloud. The noted times were 10' greater. (d) Great motion, and clouds continually passing: 1 L. hid at wires I and II. (e) 'The south-following of two equal.' (f) Clouded after wire V. (g) The counting was 1' slow: wires VI and VII have been increased 1'. (h) Great motion. (i) 'Good.' The Planet was judged to be of Mag. 8.9. (k) Very faint. (l) 'Unsatisfactory.' 2 L. hid by cloud. (m) The counting was 1' slow: correction applied. (n) The minutes set down have been diminished 1m. (o) The sky was generally cloudy this evening and sometimes completely overcast. (p) Very faint from cloud. (q) The times set down were 10' greater. (r) Close to Flora, for which it was mistaken. Both objects hid at times by clouds. (s) 'Good observation: the Planet bright.' (t) By this observation it appeared that the following object Sept. 10 was the Planet. (u) Unsatisfactory: clouds continually passing.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',344, -26',892, -13',573, -0',060, +13',618, +26',913, +40',337.

(a) Wire I lost, and wires II and III doubtful, on account of disturbance. All except wire II have been diminished 1". (b) These are grouped with T's observations, no difference of personal equation being discernible. (c) The limbs waving, and clouds continually passing. (d) 'Only one star seen.' (e) 'The south-preceding of two.' (f) 'The north-preceding of two.' (g) No object near this. (h) Irregular motion. (i) Bad definition. (k) Raggedness and much waving. All the wires of 2 L have been diminished 20". (l) The sky just clear. (m) Thorough disturbance at wires I, II, and III. (n) Flaring. (o) Cloud at wire VII. (p) Cloudy after this. (q) The counting was found to be 3" slow. All the wires have been increased 39", except wire I, which was set down 32,1 and has been altered conjecturally. (r) Quite alone: considered to be of Mag. 8,9. (s) Cloud. (t) Wires lost through mistake in the time. The counting was thought to be 1" slow: correction applied. (u) Wires I and VII, taken doubtfully through dense cloud, were rejected: wires IV, V, VI have been increased 20".

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337.

(a) The last five wires have been increased 10". (b) 'Confused and unsatisfactory.' (c) Too quickly after the Moon: these wires were considered good. (d) Cloudy. (e) Temp. 52°.3. (f) Mist. (g) Extremely faint, especially the latter. Thick fog towards the horizon. (h) 'Good: very bright.' (i) Clouds. (k) Satisfactory observation. (l) Great unsteadiness at wire VII. (m) The star observed Aug. 23. (n) 'One of greater N.P.D. precedes.' (o) 'The preceding of two stars 5° apart of nearly the same Mag. and N.P.D.' The following star is Bessel xxii. 463.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s.344$, $-26^s.892$, $-13^s.573$, $-0^s.060$, $+13^s.618$, $+26^s.913$, $+40^s.337$.

Oct. 21, between the observations of the Sun and α Aquilæ, Hardy was put forward 1^m .

(a) Cloudy. (b) Extremely faint. An object south-preceding by about $6''$ was also observed, it being doubtful which was the Planet. (c) Great tremor at wires IV and VII. (d) Very faint. (e) Thin clouds passing. (f) So much clouded as to be scarcely visible. (g) 'The following and somewhat brighter of two stars about $10''$ apart.' (h) This observation is retained for clock-error, one-third the usual weight being given to it. (i) Very cloudy. (k) Faint at times. (l) The evening was generally cloudy: no other clock-stars could be taken. (m) Dense cloud over 1 L. (n) Faint from cloud. (o) Observed satisfactorily at these wires: clouded at wires VI and VII. (p) Wire IV, written down discordantly 15,3, has been rejected. (q) Clouds just cleared off. The counting was 17^s fast: correction applied accordingly.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337.

(a) Tremor and bad definition. (b) Difficult to observe, so faint. (c) 'The brighter.' (d) Faint. (e) Another object preceding about 16" was also observed, it being doubtful which was the Planet. (f) Excessively faint: the observation mere guess. (g) The evening rainy and misty, and the stars very faint and badly defined. (h) 'A fainter of greater N.P.D. followed.' (i) Indistinct: observed doubtfully. (j) 'Low in the field?' probably by a mistake in setting. (k) Cloudy. (l) Faint from cloud. (m) 'The *nf.* star.' By Bessel the north star precedes.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337.

(a) The noted times were 24^s less. (b) 'High in the field.' The N.P.D. of H. C. is confirmed by a Circle observation. (c) Not observable at the other wires. This and the observation of Nov. 5 are used with that of Nov. 6 for azimuth error, but being taken at only one wire, are not reduced to apparent R.A. (See the calculation of azimuth errors in the Introduction.) (d) Faint. (e) 'A brighter precedes.' (f) 'The following star.' The other is Bessel XXIII. 896. (g) Quite hid at the other wires. (h) Faint from cloud. (i) Wire IV was set down 42.8 and has been altered conjecturally. (k) Cloudy. (l) Too faint to be seen at the first three wires. (m) Difficult to observe, so faint. (n) Through cloud or thick mist: very faint. (o) Faint at times. (p) 'Preceded by a brighter of Mag. 8, and of greater N.P.D.' (q) 'A brighter of Mag. 8 followed.'

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40^s.344, -26^s.892, -13^s.573, -0^s.060, +13^s.618, +26^s.913, +40^s.337.

(a) Cloud passing. (b) Tremor. (c) Cloudy. (d) 'Tempestuous weather; the clock scarcely audible.' Wire IV appears discordant. (e) Faint. (f) Not well defined. (g) The noted times have been increased 20^s. (h) Three objects taken, it being doubtful which was the Planet. (i) The observer felt unwell. (k) Corrected by +5^s for error of counting. (l) These observations prove that the third object on Nov. 23 was the Planet. (m) The evening generally cloudy. (n) Flaring. (o) Very faint. (p) Great motion. (q) The noted times were thought to be 1^s in error: correction +1^s has been applied. (r) The times for 2 L have been diminished 1^s conjecturally, the diameter by the observation being too large.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',344, -26',892, -13',573, -0',060, +13',618 +26',913, +40',337.

Dec. 5, 23^h, Hardy was put forward 1^m.

(a) Very faint. (b) After these wires the observer had to go to the Northumberland Dome. (c) 'Some large spots on the Sun.' (d) Extremely faint and at times disappearing. (e) Sometimes nearly hid by passing cloud, at other times flaring. (f) Cloudy; 2 L. observed doubtfully without the dark glass. (g) Bad image and scarcely seen. Great deposition of moisture on every part of the instrument. (h) Only seen occasionally in consequence of moisture on the eye-piece. (i) Taken by mistake for Egeria, which was not seen. (k) Bad definition and irregular motion. (l) Failure of the pencil. (m) 'Good observation.' (n) Excessively faint: moisture on the eye-piece. (o) Thick sky: only a few large stars visible. (p) Bad definition. (q) The noted times were 1^m greater.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s,344$, $-26^s,892$, $-13^s,573$, $-0^s,060$, $+13^s,618$, $+26^s,913$, $+40^s,337$.

(a) The sky had just become partially clear. (b) Very faint from clouds. (c) Hid at times by cloud. (d) After this the sky was completely clouded and rain fell. (e) No clock-stars could be observed on this day. (f) No definition. (g) Great tremor. (h) The counting was found to be 1st short: correction applied. (i) 'Good.' (k) Faint from cloud. (l) 'Several objects near this.'

MEAN RIGHT ASCENSIONS, JANUARY 1, 1850,

OF THE

FUNDAMENTAL STARS

OBSERVED IN THE YEAR 1850,

AS DEDUCED FROM EACH DAY'S OBSERVATION.

Day of Observa- tion.	Correction to Mean R.A.	Mean R.A. Jan. 1, 1850.	Day of Observa- tion.	Correction to Mean R.A.	Mean R.A. Jan. 1, 1850.	Day of Observa- tion.	Correction to Mean R.A.	Mean R.A. Jan. 1, 1850.	Day of Observa- tion.	Correction to Mean R.A.	Mean R.A. Jan. 1, 1850.

MEAN RIGHT ASCENSIONS, JAN. 1, 1850,

OF STARS

OBSERVED IN THE YEAR 1850,

AS DEDUCED FROM EACH DAY'S OBSERVATION;

AND

A CATALOGUE

OF

CONCLUDED MEAN RIGHT ASCENSIONS,

JANUARY 1, 1850;

WITH THE ANNUAL VARIATIONS.

Reference Number.	Name of Star.	Day of Observation.	Observed Mag.	Correction to Mean R.A.	Seconds of Mean R.A. Jan. 1, 1850.	Approximate N.P.D. Jan. 1, 1850.	Number of Obs.	Concluded Mean R.A. Jan. 1, 1850.	Annual Variation.	Notes.

70	α Piscium.....	Dec. 13		-2,87		81. 36	1	1. 37. 28,70	+ 3,152	Nos. 71 and 73. These two stars were represented by diagrams as having nearly the same N.P.D. The N.P.D. of the following star was obtained by a Circle Observation Nov. 25. In calculating the concluded R.A. weights are given to the results of each day proportional to the number of wires. The magnitudes were estimated Dec. 12, 1855, with the Circle Telescope. No. 72. At only two wires. No. 74. At only one wire.

ONE REVOLUTION of the MICROMETER = 20",850. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

Jan. 7, 0^h. The Circle was taken from the wall, and the pivots were cleaned. At the same time the object-glass was taken out and cleaned, the Telescope was shifted on the Circle, and the Microscopes were adjusted.

Jan. 17, 13^h. The micrometer-wire was adjusted equatorially.

(a) This Zenith Point was obtained Dec. 31, 1849. (b) Bisected hurriedly, the Transit observation being taken by the same observer. (c) Disturbance of the mercury by wind. (d) Between these the eye-piece was taken out to oil the micrometer-screw and adjust the comb. (e) Steady. (f) 'A little rugged.' (g) The Limbs very faint, and the bisections doubtful. (h) Negative correction for Runs. (i) 'The north-following of two.' (k) Very faint from cloud. (l) 'Followed by two of less N.P.D.'

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refrac-tion.	Apparent N.P.D. from the Observation.			Observer.

ONE REVOLUTION of the MICROMETER = 20",850. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Negative correction for Runs. (b) The mercury much agitated by wind. (c) Cloudy. (d) The pointer reading has been diminished 1'.
 See Feb. 11. (e) The readings of B and F have been corrected respectively by +4",8 and +2",2, the positive divisions having been inadvertently bisected by these microscopes. See in the Introduction the Runs of Feb. 19, which were taken in this position of the Circle. (f) 'Good.' (g) Clouded and unsteady.
 (h) Faint from cloud. (i) Cloudy: star scarcely visible. (k) The northern of two very faint. (l) Delay by the Circle slipping after a fit at bisection. (m) Rather ragged. (n) Dense cloud. (o) The northern and brighter of two. (p) Very faint. 'One of the same magnitude preceded high in the field.'

ONE REVOLUTION of the MICROMETER = 20",850. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Negative correction for Runs. (b) Times of bisectinn by Molyneux. 6^b. 22^m. 42^s and 6^b. 24^m. 9^s. By a Circle transit March 11, Molyneux was 2^m. 2^s fast. (See the Circle transits in the Introduction.) (c) Extremely faint. (d) Observed for H. C. 14336. (e) This is Σ 1237; it was not observed to be double. (f) No object near this. (g) 'A very faint star of greater N.P.D. followed.' (h) Σ 1297, 'observed as single.' The small star was probably invisible in the illumined field. (i) Extremely faint; observed for H. C. 14817.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refrac- tion.	Apparent N.P.D. from the Observation.			Observer.

ONE REVOLUTION of the MICROMETER = 20",850. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Unsatisfactory observation, the mercury being agitated by wind. (b) 'This precedes the next about 1½ interval.' (c) The Pointer reading has been diminished 2". (d) Waving. The barometer not being read, the assumed reading is the mean between the readings 29",860 and 29",931, which were taken three hours before and after noon. (e) 'Beautifully steady.' (f) The bisection not good, a strong south wind blowing. (g) Clouded and faint. (h) Misty sky. (i) 'A star preceding this.' (k) Negative correction for Runs. (l) Clouded: scarcely visible. (m) Diffused. (n) Cloudy. (o) Very faint. (p) Very faint from mist. (q) Bad definition. (r) Too faint for satisfactory observation.

ONE REVOLUTION of the MICROMETER = 20",850. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) The mercury disturbed. (b) Faint. (c) 'One of Mag. 5.6 and of less N.P.D. following by 20"' viz. B.A.C. 3337. (d) This star was noticed in taking the transit of H. C. 22079 on April 25. (e) A mist had suddenly come over, which made the Moon faint at intervals. (f) Faint from day-light. (g) Cloudy at this time and during the remainder of the night. (h) Great motion. (i) 'One of Mag. 9 and less N.P.D. follows 10"' (k) 'Not well defined, but pretty good observation.' (l) Very faint at intervals from cloud.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refrac-tion.	Apparent N.P.D. from the Observation.			Observer.

ONE REVOLUTION of the MICROMETER = 20"850. ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Observed hurriedly. (b) The Planet bright and no object near. (c) 'Good.' (d) The third comet discovered by M. Petersen. The Comet was faint, but the bisection was considered good. Correction applied for change of N.P.D. = -1",41. (e) 'Very faint.' Probably the companion, Bessel xiii. 516, which is much fainter, was not visible. (f) The mercury greatly disturbed. (g) Negative correction for Runs. (h) The Planet faint, but the observation not uncertain. (i) Faint and disappearing at times. (k) Excessively faint. Times by Molyneux, 1^h. 9^m. 10^s and 1^h. 11^m. 0^s. By Circle transits June 3 and 7, Molyneux was 3^m. 41^s fast. (l) The Planet bright and the observation satisfactory. (m) Seen only at intervals and the bisection doubtful. (n) The Pointer reading has been diminished by 1'. (o) 'The nucleus pretty well seen, but difficult to bisect.' The correction applied for change of N.P.D. = -2",34. (p) Very faint. (q) 'Satisfactory.' (r) Much diffused. (s) The Pointer reading was greater by 10'.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refraction.	Apparent N.P.D. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20",850.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.

(a) Negative correction for Runs. (b) Faint from clouds. (c) The companion of β Scorpil. (d) The recorded Pointer reading was 1" less: alteration conjectural. (e) Clouded and faint at times. (f) Beautiful definition: the sky covered with light clouds. (g) Badly defined. (h) Waving. (i) Ragged.

ONE REVOLUTION OF THE MICROMETER = 20",850. From July 3 = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6. ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

July 3, the Circle was taken from the wall to clean the pivots, the Microscopes were adjusted, the distance of the wire-frame from the object-glass was altered, and the Azimuth Error was corrected. (See the Introduction.) The Micrometer-wire was adjusted equatorially on July 4 after the observations.

(a) Negative correction for Runs. (b) The reading of E, being omitted, is supplied so as to differ from the mean by the same quantity as in the observation of N.L. (c) Very unsteady. (d) Clouded. N.L. lost by clouds and the clamp failing. (e) Very faint: bisection quite doubtful. (f) The Circle reading has been diminished 5". (g) Not well defined. (h) Times by Molyneux, 18^h. 11^m. 30^s, 18^h. 16^m. 8^s, 18^h. 20^m. 44^s, 18^h. 25^m. 45^s, and 18^h. 29^m. 56^s. M fast on H. 39°. (i) The micrometer reading was by mistake set down 8",470. (k) Faint. (l) This Zenith Point is deduced from the observations of δ Ursæ Minoris. (m) Cloudy. (n) 'Pretty good.' (o) Waving and flaring. (p) After the observations of July 5 the micrometer wire was adjusted more exactly. (q) Circle not clamped. Microscope A being moved before it was read off, the reading is supplied as on June 25. (r) Extremely faint: the bisection doubtful. (s) July 8, 4^h the wires of Microscope E were accidentally broken. After replacing them the Zenith Point was taken. (t) Bisection not good: the tangent-screw failed.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) The division in advance having been bisected with microscope F, the correction + 2",3 for its Run, which was taken after replacing the Circle, has been applied. (b) Negative correction for Runs. (c) Very misty. (d) Faint from cloud. (e) The Circle reading has been increased 5'. (f) Bi-section of N.L. more satisfactory than that of S.L. which was very ragged. (g) Rather tremulous. (h) Clouded but well bisected. (i) 'Good.' (k) The micrometer reading was 10' greater. (l) Clouded but steady. (m) Cloudy. (n) 'Not good.' (o) 'Good observation.'

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Cloudy. (b) 'The north-preceding of a coarse double star: the components equal.' This is Σ 2217. (c) Hid by cloud at the direct observation.
 (d) Without the dark glass. (e) Rather faint, but the observation not doubtful. (f) Very steady. (g) N.L. lost by a mistake in setting. (h) The sky was much overcast during the months of July and August. (i) Negative correction for Runs. (k) 'Appeared oblong.' (l) Faint from cloud.
 (m) The Planet was seen only a few seconds. (n) The mercury unsteady. (o) Bad definition. (p) Faint, and clouds passing. The micrometer reading has been diminished by 1" conjecturally. (q) 'Of Mag. 11.12' see the transit observation. A preceding and brighter object was also bisected.
 (r) Observed by Mr John W. Breen. (s) After this the sky was completely overcast.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Very faint from cloud: not seen at the 5th wire. (b) Much clouded at first, but well observed at the 4th and 5th wires. (c) Times by Molyneux, 18°. 30'. 40" and 18°. 31'. 56". M fast on H, 50". The corrections applied for curvature of path are +0",48 and -1",16, which were found by special calculation. (d) Negative correction for Ituna. (e) Dense mist coming over. (f) 'Very cloudy and the star faint.' (g) Cloudy. From Aug. 19 to Sept. 7 the Transit and Circle observations are nearly all taken by the same observer. (h) The Limb was much clouded and very ill-defined, and the bisection quite doubtful. (i) Barely visible from cloud. (k) Delayed by the transit observation and taken doubtfully. (l) Waving. (m) The micrometer reading, which was set down 10",000, is assumed to be the same as for the observation of the Sun. (n) 'Good.' (o) 'The Limb was barely full.' (p) Without the dark glass. (q) Not good: bisected hastily to have time for taking the transit of 2 L.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Unsteady, and scarcely visible from haze. (b) Too faint to be seen earlier: the observation was extremely doubtful. (c) Negative correction for Runs. (d) The limbs ragged and very unsteady. (e) Waving. (f) Observed hurriedly. The Planet was considered to be of Mag. 8.9. (g) 'Good.' (h) The circle reading was 5' greater. (i) Very faint: not visible at the other wires. (k) Before this observation the Pointer was adjusted: it had pointed 5' in advance. (l) Faint. (m) Mist. (n) 'Very bright: of Mag. 8.'

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) A close double star, observed as single. (b) Negative correction for Runs. (c) 'Very good.' Delay by the transit observation. (d) Very unsteady.
 (e) Rugged and rather unsteady. (f) Bright. (g) 'Good.' (h) Very faint from cloud. 'The north-preceding of two 10" apart.' (i) Very indefinite; the mercury unsteady. (k) Steady and well defined. (l) Assumed to be taken on the micrometer wire as left in the observation of the Moon.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) 'The north preceding of two.' The other is H. C. 37096. (b) Too much clouded for satisfactory observation. The degrees of the Pointer reading have been altered conjecturally from 130° to 139°. (c) Very faint from cloud. (d) 'Good.' No object near. (e) Hid before by cloud. (f) 'One of Mag. 8 and less N.P.D. preceded.' (g) 'Preceded by an equal one of less N.P.D.' (h) 'The northern and brighter.' The other is Bessel xxi. 296. (i) Very faint. (k) 'No object near this.' (l) The Pointer reading has been diminished 10°. (m) Negative correction for Runs. (n) 'Of Mag. 9.' (o) 'Both bisected, being of the same N.P.D.' (p) 'Good.' (q) Unsteady. (r) 'A fainter of less N.P.D. followed.' (s) Several other objects of greater N.P.D. in the field. (t) 'One rather brighter of greater N.P.D. preceded.' (u) 'The following of two.' (v) Faint, but the observation not doubtful.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) 'Two preceding.' (b) Unsteady. (c) Negative correction for Runs. (d) Excessively faint and difficult to bisect. (e) The sky was very thick this evening: Neptune not seen. (f) Too faint for certainty of bisection. (g) The Circle reading has been increased 5'. (h) Too faint to be well observed. (i) 'A brighter north-preceding.' (k) 'A brighter object of greater N.P.D. preceded 3 or 4 seconds.' (l) Time by Molyneux, 13h. 8m. 11s. By the times of transit of zodiacal stars, noted for the sake of identifying the stars, Molyneux was ascertained to be 42s. fast. (m) One limb lost by wrong setting. (n) The Circle reading has been increased 1', to agree with H. C. and an observation in 1852. (o) The Circle reading has been diminished 4'. (p) 'Precedes β Capricorni about 10,' but was bisected later. (q) Faint from passing clouds. (r) Seen only at this wire. (s) Seen through a break in the clouds. (t) Dense cloud; the Moon barely visible, especially at the 1st and 5th wires.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for S.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refraction.	Apparent N.P.D. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) 'A brighter object of less N.P.D. preceded.' (b) Negative correction for Runs. (c) Seen only occasionally through clouds. (d) Seen with difficulty through cloud. (e) Assumed to be taken on the micrometer wire as left in the preceding observation. (f) Clouded; almost too faint with the dark glass and too bright without. (g) Faint; bisection doubtful. (h) The middle and faintest of three objects, the last of which was afterwards found to be H. C. 46040. (i) 'A brighter of greater N.P.D. follows.' (k) A brighter object lower in the field was noticed. (l) Very faint from cloud. (m) Observed hurriedly: the shutters could not be opened earlier.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) A following and fainter object was also bisected. (b) Very faint. (c) 'A brighter of greater N.P.D. following.' (d) 'Precedes the next about 30'.' (e) 'The preceding is the brighter.' The other was taken for Flora. (f) 'Precedes the next about 37'.' (g) Very unsteady. (h) Mistaken for Flora. (i) Very faint: the bisection uncertain. (k) Faint from cloud. (l) 'One of greater N.P.D. and equal magnitude followed.' The Circle reading was 10' less. (m) These observations uncertain, the circle being covered with moisture. (n) The wires of Microscope E having been deranged by pushing in the eye-piece too far, the readings of that and the opposite Microscope F are omitted. (o) Good bisections. (p) Observed for Flora through a mistake of 5' in the setting. (q) Negative correction for Runs. (r) The division bisected by Microscope B was obscured by a patch of rust or dirt. (s) 'Precedes the next about 10'.' (t) The Runs and Zenith Point used Nov. 2 were deduced for four Microscopes from those taken on Nov. 6.

ONE REVOLUTION of the MICROMETER = 20",860. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) The mercury waving and bisection quite uncertain. (b) The tangent-screw was inadvertently turned after the observation of S.L. (c) Negative correction for Runs. (d) 'The only object seen.' The sky was too cloudy for farther observations. (e) Very bad definition. The setting of the micrometer-wire to 10",000 was inadvertently omitted. Perhaps the micrometer reading for the Sun was 10",397. (f) The circle reading has been diminished 1". (g) This limb was thought to be more illuminated than the other: neither appeared full. (h) 'Of Mag. 9.10.' (i) Very faint. (k) The mercury tremulous. (l) Misty cloud: the night generally unfavorable for observing. (m) 'The faintest of several.' (n) The Circle reading has been increased 4". (o) Faint from cloud.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runo for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refrac- tion.	Apparent N.P.D. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20'',860. ONE INTERVAL from the middle wire for an Equatorial Star = 16'',6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8'',00.

(a) Faint from cloud. (b) Very steady. (c) Extremely unsteady and badly defined. (d) 'Good bisection.' (e) Very tremulous.
 (f) 'Hurried; not good.' An object of the same R.A. lower in the field was noticed. (g) Negative correction for Runs. (h) These observations quite uncertain on account of mist from the breath of the observer on the eye-glass. (i) Placed by guess opposite the hole of the comb: the observation is probably worthless. (k) The barometer reading, being unusually large, was verified by the observer. (l) 'Unsatisfactory bisection.' (m) Negative correction for Runs. The adopted zenith point is 66°. 25'. 16'',16. (n) Faint. The direct observation is discordant.

MEAN NORTH POLAR DISTANCES OF THE STARS

OBSERVED IN THE YEAR 1850,

AS DEDUCED FROM EACH DAY'S OBSERVATION;

AND THE

CONCLUDED MEAN NORTH POLAR DISTANCES,

JANUARY 1, 1850;

WITH THE ANNUAL VARIATIONS.

No. 4. There is no star in the place of Bessel o. 29. See the note to the observation.

No. 8. The R.A. of Bessel o. 161, which is the same star, is 10^s too great.

Nos. 31 and 32. The former is decidedly the brighter. According to Bessel both are of Mag. 9.

No. 33. There is no star in the place of H. C. 867, which appears to be the same as H. C. 876, with an error of 13^s in defect in R.A.

No. 37. This N.P.D. appears to be quite discordant. See the note to the observation.

No. 249. By an Equatorial observation on Dec. 12, 1855, the R.A. of this star in the Hist. Ccl. was found to be 30° too small.

No. 260. The minutes of the N.P.D. were verified by a circle observation Feb. 16, 1853. The N.P.D. of H. C. is 1' less.

No. 264. The N.P.D. agrees with that of H. C. 14336. The R.A. was found by an Equatorial observation on Dec. 12, 1855. The R.A. of H. C. appears to apply to the star observed with the transit on March 16, the magnitude of which as seen on Dec. 12, 1855 was about the 9th.

No. 286. Observed for H. C. 14817. It was ascertained by Equatorial observations Dec. 12, 1855, and March 13, 1856, that there is no star in the place of H. C. 14817.

No. 340. This N.P.D. agrees with one obtained in 1851. Bessel's appears to be 30" too great.

Nos. 653 and 654. Observed with Parthenope with the Northumberland Equatorial the same night. The R.A. of the former is inferred from the Equatorial comparisons.

No. 658. The correction of the Pointer reading mentioned in the note to the observation, was verified by a circle observation March 27, 1856.

No. 671. The magnitude in B.A.C. is 4½.

HORIZONTAL AND VERTICAL MEASURES
OF THE
DIAMETERS OF THE SUN AND MOON,
COMPARED WITH TABULAR DIAMETERS:
AND
RIGHT ASCENSIONS AND NORTH POLAR DISTANCES
OF THE SUN, THE MOON,
THE PLANETS FLORA, VICTORIA, IRIS, HEBE, PARTHENOPE, HYGEIA,
EGERIA AND NEPTUNE, AND PETERSEN'S THIRD COMET,
CONCLUDED FROM
OBSERVATIONS WITH THE TRANSIT AND MURAL CIRCLE,
AND COMPARED
WITH CALCULATED RIGHT ASCENSIONS AND NORTH POLAR DISTANCES.

1850.

I. SIDEREAL INTERVALS occupied by TRANSITS of the SUN'S DIAMETER, and VERTICAL DIAMETERS of the SUN corrected for REFRACTION and PARALLAX; compared with the values in the NAUTICAL ALMANAC.

Day of Observation.	Interval by Observation.	Seconds of Tabular Interval.	Excess of Tabular Interval.	Vertical Diameter by Observation.	Seconds of Tabular Diameter.	Excess of Tabular Diam.	Day of Observation.	Interval by Observation.	Seconds of Tabular Interval.	Excess of Tabular Interval.	Vertical Diameter by Observation.	Seconds of Tabular Diameter.	Excess of Tabular Diam.

Jan. 26, Feb. 22, and March 28. By calculation the observed Limb was found to be full.

Feb. 26. The correction applied to the N.P.D. of N.L. for defect of illumination = - 0",44.

April 25. The correction applied to the R.A. of 2 L. for defect of illumination = + 0",15.

Aug. 20. The N.P.D. was quite uncertain. See the note to the observation.

Aug. 21. The correction applied to the R.A. of 1 L. for defect of illumination = - 0",03.

The Transit observation on June 3 was taken very doubtfully at only two wires.

DETERMINATION OF THE POSITION OF THE ECLIPTIC, AND OF THE MEAN ERROR OF
THE ASSUMED RIGHT ASCENSIONS OF THE FUNDAMENTAL STARS, FROM THE
TRANSIT AND CIRCLE OBSERVATIONS OF THE SUN IN THE YEAR 1850.

The total number of Circle Observations of the Sun, in which both Limbs were observed, was 111, excluding that of Nov. 15, and the number of observations of single Limbs, excluding that of Aug. 20, was 15. The observations of single Limbs are taken into account, giving half-weight to each. The whole are divided into four groups containing $29\frac{1}{2}$, 30, 29 and 30 observations. Each of these has been subdivided into three groups, as exhibited in the subjoined Table. This Table contains also the limiting days and the mean day of each group, the mean value (α) of the Tabular Errors in North Polar Distance, derived from the columns in pages 280—282, and the Sun's Longitude (λ) and North Polar Distance (Δ) at the mean noon of the mean day.

Limiting Days of Observation of each group.	Mean Day.	Mean of the Tabular Errors in N.P.D.	Number of Observations.	Sun's Longitude at mean Noon of mean Day.	Sun's N.P.D. at mean Noon of mean Day.

Formula of Calculation.

$$\alpha + m \cos \lambda \operatorname{cosec} \Delta + n \sin \lambda \operatorname{cosec} \Delta + p = 0.$$

The following equations were deduced from this formula by means of the data in the Table above. Each equation is multiplied by the respective number of observations, with the exception of the first equation, to which the weight 9 is given, to make the weights the same in the alternate Quarters.

$$\begin{array}{lcl}
 \text{First Quarter} & \left\{ \begin{array}{l} \text{Feb. 12.....} - 0,48 + m \times 7,4447 - n \times 5,5129 + 9p = 0. \\ \text{Mar. 17.....} + 1,70 + m \times 9,9849 - n \times 0,5996 + 10p = 0. \\ \text{Apr. 23.....} + 0,40 + m \times 8,5951 + n \times 5,5716 + 10p = 0. \end{array} \right. \\
 \text{Second Quarter} & \left\{ \begin{array}{l} \text{May 27.....} + 1,80 + m \times 4,4026 + n \times 9,7876 + 10p = 0. \\ \text{June 15.....} - 2,80 + m \times 1,1462 + n \times 10,8290 + 10p = 0. \\ \text{July 7.....} + 0,10 - m \times 2,7925 + n \times 10,4686 + 10p = 0. \end{array} \right. \\
 \text{Third Quarter} & \left\{ \begin{array}{l} \text{Aug. 2.....} - 8,50 - m \times 6,7186 + n \times 8,0740 + 10p = 0. \\ \text{Aug. 22.....} - 3,33 - m \times 7,8805 + n \times 4,7387 + 9p = 0. \\ \text{Sept. 13.....} - 18,10 - m \times 9,8795 + n \times 1,6872 + 10p = 0. \end{array} \right. \\
 \text{Fourth Quarter} & \left\{ \begin{array}{l} \text{Oct. 11.....} - 2,61 - m \times 8,6325 - n \times 2,7747 + 9p = 0. \\ \text{Nov. 5.....} - 3,30 - m \times 7,6269 - n \times 7,0503 + 10p = 0. \\ \text{Dec. 10.....} + 5,94 - m \times 2,4542 - n \times 11,6887 + 11p = 0. \end{array} \right.
 \end{array}$$

From the above, new equations are formed by adding and subtracting as indicated below:

$$\begin{array}{l}
 \text{First Quarter} + \text{Second} + \text{Third} + \text{Fourth} \\
 - 29'',18 - m \times 14,4112 + n \times 23,5305 + 118p = 0. \\
 \text{First Quarter} + \text{Second} - \text{Third} - \text{Fourth} \\
 + 30'',62 + m \times 71,9732 + n \times 37,5581 = 0. \\
 \text{First Quarter} - \text{Second} - \text{Third} + \text{Fourth} \\
 + 32'',48 + m \times 29,0334 - n \times 67,6397 = 0.
 \end{array}$$

The solution of these equations gives,

$$m = -0''.552, \quad n = +0''.243, \quad p = +0''.131.$$

Let $\delta\lambda$ = the mean excess for the year of the Tabular Longitude of the Sun above the true Longitude.

δR = the mean excess for the year of the Tabular R.A. of the Sun above the true R.A.

$\delta\Delta$ = the mean excess for the year of the Tabular N.P.D. of the Sun above the true N.P.D.

δI = the mean excess of the Obliquity (I) assumed in the Tables above the true Obliquity.

$A = -0^s.140$, which is the mean of 130 apparent excesses of the Tabular R.A. in pages 280—282, half-weight being given to observations of single limbs and to the observation of both Limbs taken on Aug. 24 at only five wires.

$D = -0''.026$, which is the mean of 126 apparent excesses of the Tabular N.P.D. in pages 280—282, half-weight being given to observations of single limbs.

q = the mean excess of the assumed R.A. of the fundamental stars above the true R.A.

p = the mean excess within the Tropics of the N.P.D. determined by the Circle observations and calculations of 1850 above the true N.P.D.

Then, $\delta\lambda = m \operatorname{cosec} I = -0''.552 \times \operatorname{cosec} 23^\circ.27'.5 = -1''.387$.

$$\delta R = \frac{\delta\lambda}{15} \times \frac{\sum \cos I \operatorname{cosec}^2 \Delta}{2\pi} = \frac{\delta\lambda}{15} \text{ nearly} = -0^s.092.$$

$$\delta\Delta = (\text{Tabular N.P.D.} - \text{Observed N.P.D.}) + (\text{Observed N.P.D.} - \text{True N.P.D.})$$

$$= D + p = -0''.026 + 0''.131 = +0''.105.$$

$$\delta I = n \sec I = +0''.243 \times \sec 23^\circ.27'.5 = +0''.265.$$

$$q = (\text{Tabular R.A.} - \text{True R.A.}) - (\text{Tabular R.A.} - \text{Observed R.A.})$$

$$= \delta R - A = -0^s.092 + 0^s.140 = +0^s.048.$$

Hence the assumed R.A. of the fundamental stars are too great by the mean quantity $0^s.048$.

OCCULTATIONS
OF
FIXED STARS AND THE PLANET JUPITER
BY THE MOON,
WITH
THE EQUATIONS GIVEN BY THE CALCULATION
OF THE OCCULTATIONS.

1850.

COMPARISONS OF CHRONOMETERS WITH THE TRANSIT CLOCK, USED IN THE
CALCULATION OF THE FOLLOWING OCCULTATIONS.

* * THE letter *H* is an abbreviation for Hardy, the Transit Clock. *U* and *X* are Sidereal Chronometers, and *W* is a Solar Chronometer, each beating half-seconds.

(a) 'Beautifully exact: the star bright.' (b) Seen at the instant of reappearance. The Moon was extremely steady, and the Limb and star were sharply defined. (c) 'Very exact.' (B). 'Good.' (C). (d) The times were considered exact. These occultations are not in the Nautical Almanac. The angle from the North Point was estimated at 100° in the observation of Feb. 16, and at 60° in that of Feb. 18. The star (α) was not found in any Catalogue. Its mean place 1850,0, as determined by Equatorial observations on Sept. 22, 1856 is as follows: R.A. = $3^h.3^m.50^s.14$, N.P.D. = $78^\circ.52'.40''.90$. (e) 'Pretty good.' The instrument, not being noted, is put down conjecturally. (f) 'Very exact. The circumstances favorable: clouds had passed off.' (B). T expected the star to appear higher, but considered the observation good. (g) Jupiter was very faint from clouds, especially as seen with the 5-feet Telescope. B noticed that at the time of first contact the Limb of Jupiter was elongated towards the Moon's Limb. The time noted by T was 'when a small dark projection was seen on the edge of the Planet,' and is probably too late for first contact. 'Total immersion not very good: cloudy at the time.' (T). The Planet appeared to B to be quite obscured by cloud before the total immersion. (h) Both times were thought to be nearly exact. No distortion of the Planet was noticed, but it appeared to hang a little on the Moon's Limb, and the recorded time of total emersion is that of final separation. (i) The Moon waving and low, but B's observation was not doubtful. T kept the star in view, although extremely faint, till it appeared to touch the Moon's Limb, and thought the time 'pretty accurate.' Possibly an error of 20' in counting. (j) Both observations quite satisfactory. (k) 'Good, I think, and circumstances favorable.' (B). 'The disappearance was nearly at $22^h.0$; I feel doubtful whether it was $0^h.2$ before or after, but I think it was before.' (C). (l) 'Seen, I think, at the very instant of emergence.' (B). The star was first seen by C at $11.10.43.0$ W when it was a few seconds distant from the Limb, and at $11.10.55.0$ W it was judged to be at twice the distance. The time of reappearance is hence inferred, with some degree of uncertainty, to be $11.10.31.0$ W. (m) The Moon's Limb waving, but the observation not doubtful. (n) 'Beautifully exact. I saw the star projected on the Moon's bright Limb full five seconds before it disappeared. Magnifying power, 215.' (B). (o) 'Extremely exact. The sky clear, and the star blazing a little.' (B). 'Good.' (T). (p) 'Very exact: I saw the star coming out, and fancied I saw a projection.' (B). 'I believe good, but the star excessively faint: it had not separated from the Limb at the noted time.' (T). (q) 'Exactly at the second: T counted. The Moon was very low, but the observation not doubtful. The star appeared to remain several seconds on the Limb, but the power used being not higher than 35, it was uncertain whether it had actually come in contact.' (C). 'The eye-glass obscured by mist and the star very faint in consequence.' (B). Probably the time by B does not apply to the disappearance by the occultation. (r) 'Dense clouds covering the Moon: the star when first seen was separated from the Limb.' (B). The calculation of this occultation is not added. (s) 'I believe quite exact.' (T). 'I did not see the star at its first appearance.' (B). (t) 'Pretty good: the star very faint.' (T). B's observation with the Northumberland Telescope was quite satisfactory. (u) The mean place 1850,0 of this star, as inferred from Equatorial observations taken Sept. 23, 1856 is, R.A. = $6^h.3^m.4^s.69$, N.P.D. = $70^\circ.12'.2''.07$. (v) T's observation was considered 'very exact.' B was perplexed by the observation of the appearance of the small star (β).

Disappearance of γ Tauri, Jan. 23, $5^h.6^m.15^s.07 + t^s + \tau^s$ Greenwich Mean Solar Time.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',344, -26',892, -13',573, -0',060, +13',618, +26',913, +40',337.

(a) Cloudy. (b) The difference of personal equation of B and T, which appears to be variable, was not taken into account in determining the clock's rate on Jan. 4. (c) Interruption by failure of the pencil. (d) Cloudy soon after. (e) The sky had recently cleared: stars very badly defined. (f) Loud wind made the clock inaudible. (g) The last three wires have been increased 1". (h) Very tremulous. (i) Wires lost by failure of the observer's lamp. (k) Very faint from clouds. (l) Bad illumination of the field. (m) Cloudy after this. (n) Tremor. (o) Hardly visible, and extremely unsteady. (p) The times set down have been increased 1". (q) Faint from cloud. (r) A spot near the West Limb passed wire VI at 20^h. 11^m. 5^s. (s) In estimating the rates for Jan. 21 and Jan. 22, B is supposed to observe earlier than T by 0^s.2.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^{\circ}344$, $-26^{\circ}892$, $-13^{\circ}573$, $-0^{\circ}060$, $+13^{\circ}618$, $+26^{\circ}913$, $+40^{\circ}337$.

Jan. 24, after the Sun, Hardy was put forward 1^m .

(a) 'Several in the field.' (b) Obscured by cloud, but observed satisfactorily. (c) Seconds not taken from the clock. The clock-error being discordant is not used. (d) 'Very good.' (e) Great motion. (f) Each wire has been diminished 1^s . (g) The observer was delayed at the Northumberland Dome. (h) The noted time was 1^m greater. (i) 'A fainter of nearly the same N.P.D. follows.' (j) Bright at first but clouded at the last wires: the observation was considered good. (k) Very faint. (l) Cloudy at times. (m) Till this time the night had been cloudy. (n) Bad definition. (o) 'High in the field.' (p) Invisible at times from passing cloud. (q)

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40^s.344, -26^s.892, -13^s.573, -0^s.060, +13^s.618 +26^s.913, +40^s.337.

(a) Invisible at times from passing cloud. (b) Very cloudy: the observation mere guess. (c) In estimating the rate for this day, B is supposed to observe earlier than T by 0.2. (d) 'A brighter south-precursor.' (e) 'The north-following and brighter of two.' (f) The counting was 5^s fast. Soon after this observation the sky was overcast. (g) 'Surrounded by a corona.' (h) Obscured by cloud. (i) Faint from cloud. The noted time was 5^s greater. (k) 'The south-precursor of two.' (l) 'One of the same magnitude and less N.P.D., follows about 2^s, viz. H. C. 12375. (m) 'A fainter of the same N.P.D. preceded considerably.' (n) Very faint from cloud: hid at the other wires.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40^s,344, -26^s,892, -13^s,573, -0^s,060, +13^s,618, +26^s,913, +40^s,337.

(a) Partly without the dark glass. (b) Faint from cloud. (c) The last three wires of 2 L. without the dark glass, but the light was dazzling. The observer noticed some very large spots. (d) 'The north-following and brighter of two.' (e) Observed confusedly at first: wire IV, written down 47,2, has been rejected. (f) 'A brighter lower in the field.' See Feb. 4. (g) 'The north-preceding of two equal objects: good observation.' (h) 'Not quite full.' (i) The observer was delayed at the Circle. (k) 'Several large spots on the Sun.' (l) The noted times were 1^s less. (m) Much obscured by cloud. (n) Clouds: the observation unsatisfactory. (o) Seen through dense cloud: too ill-defined and unsteady for accurate observation.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s,344$, $-26^s,892$, $-13^s,573$, $-0^s,060$, $+13^s,618$, $+26^s,913$, $+40^s,337$.

March 12, 22^h, Hardy was put forward 1^m. The hand moved very stiffly, and the rate appears to have been altered.

(a) 'A fainter of greater N.P.D. precedes by about 10^s.' (b) 'Good.' (c) The evening had been cloudy. (d) Cloudy. (e) 'One of Mag. 8 and greater N.P.D. preceded.' (f) 'Coarsely double: the companion of Mag. 9.10 and southward.' (g) 'A fainter higher up,' viz. Bessel VIII. 586. (h) 'Two others south-following.' (i) 'Of the same magnitude as the preceding and of less N.P.D.' (k) 'Good.' The Planet was considered to be of Mag. 9. (l) A large and ill defined mass of light. (m) 'Coarsely double: the companion south-following.' (n) 'Faint: the most southern of three.' (o) 'A fainter preceding.' (p) Bad definition. (q) Clouds passing.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40^s,344, - 26^s,892, - 13^s,573, - 0^s,060, + 13^s,618 + 26^s,913, + 40^s,337.

(a) 'A brighter of greater N.P.D.' (b) Faint from cloud. 'A brighter south-following.' (c) Not well defined. (d) High wind.
 (e) 'The north-preceding and fainter of two objects a little apart.' (f) In estimating the Clock's rate for this day, B is assumed to observe earlier than T by 0^s,3. (g) 'The brightest and most southern of three.' (h) 'One of equal magnitude south-preceding.' (i) Cloudy. (k) Faint from cloud.
 (l) Wire IV has been increased 1^s. The Planet was extremely faint and difficult to observe, the sky being still cloudy. (m) Much obscured by cloud.
 (n) The observer thought the counting was 1^s fast; alteration made accordingly. (o) Clouded till wire III; then flaring and badly defined. (p) The last three wires have been diminished 1^s, the observer was confused at wire V.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°, 344, - 26°, 892, - 13°, 573, - 0°, 060, + 13°, 618, + 26°, 913, + 40°, 337.

(a) 'Good observation.' (b) Cloudy. (c) Used for clock-error, 0,09 being added to the R.A. of the Nautical Almanac. (See Introduction).
 (d) Quite cloudy soon after. (e) 'Good.' (f) 'Good observation: no object near this.' (g) 'One of Mag. 7½ north-following,' viz. Bessel ix. 1017.
 (h) 'A brighter followed at an interval of 24.' (i) 'Followed by a bright star of nearly the same N.P.D.' (k) 'One of equal magnitude north-preceding.'
 (l) The counting was 1 less. (m) The counting was 1 more. (n) Faint, being near the Moon. (o) 'One of equal magnitude south-preceding.'

ILLUMINATION EAST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40",344, -26",892, -13",573, -0",060, +13",618, +26",913, +40",337.

April 17, 2^h, Hardy was put forward 1^m.

(a) Observed confusedly: 1^s has been deducted conjecturally. (b) 'The north-following of two equal.' The other is B.A.C. 4134. (c) A fainter of greater N.P.D. was noticed. (d) Reduced to Mag. 6 by cloud. During the previous observations the sky was covered with thin cloud which gradually became denser. (e) Cloudy. (f) 'Not good: too cloudy.' (g) 'One rather fainter precedes.' (h) Wire IV. is discordant. The N.P.D. of this star, which was taken for H. C. 22162, is uncertain. (i) Very faint from thick cloud. (k) Very unsteady. (l) Cloudy southward. (m) 'The north-following star.' (n) The counting was 10^s less. (o) The counting was 6^s less, not being taken from the clock. (p) Faint from thick cloud. (q) 'Good observation.' (r) 'Seen only at this wire: a brighter object somewhat higher in the field.'

ILLUMINATION EAST. From May 6, ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,344, -26°,892, -13°,573, -0°,060, +13°,618, +26°,913, +40°,337. From May 6, -40°,337, -26°,913, -13°,618, +0°,060, +13°,573, +26°,892, +40°,344.

(a) Cloudy. (b) Cloudy, and the star unsteady. (c) Bad definition. (d) Clouds passing. (e) The observer felt unwell. (f) The counting was found to be 9th fast; the first four wires have been diminished 10th, and the last two 9th. (g) 'Too faint.' (h) 'Quite uncertain.' (i) Very faint at times. (k) 'Wire IV quite uncertain.' (l) Scarcely visible from clouds. (m) Faint.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^{\circ}337$, $-26^{\circ}913$, $-13^{\circ}618$, $+0^{\circ}060$, $+13^{\circ}573$, $+26^{\circ}892$, $+40^{\circ}344$.

(a) Cloudy. (b) Faint and at times invisible. (c) The counting was 1^s less. (d) In calculating the mean clock-error, weights are given to these in proportion to the number of wires. (e) 'A brighter south-following,' viz. χ Virginis. (f) 'The most southern of three.' (g) Scarcely visible from clouds. (h) 1 L. hid by cloud. (i) Clouds passing: wires V and VI of 2 L. without the dark glass. (j) Faint from cloud. (k) 'One of Mag. 9.10 south-preceding, and another of Mag. 8 south-following by about 19'. Nothing seen in the place of H. C. 23657. (l) 'Good observation.' (m) 'The south-following of two equal.' (n) 'One equal of less N.P.D. follows.' (o) Wire VII was written down 19,9. (p) Wire III doubtful from clouds. (q) 'One of Mag. 8 south-following.' (r) 'One of Mag. 9 north-preceding, and another of Mag. 8 north-following.' (s) Very faint. 'One of Mag. 9 north-preceding, and another of Mag. 8 north-following.' (t) 'The north-preceding of two: not a good observation.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',337, -26',913, -13',618, +0',060, +13',573 +26',892, +40',344.

(a) All except wires I and II have been decreased 5". (b) Very faint and unsteady. (c) 'After wire IV the Telescope was accidentally struck on the west side.' No perceptible effect was found by reducing the last three wires separately. (d) Clouded at times and very unsteady. (e) Clouds. (f) Day-light too strong. (g) Scarcely visible at times. (h) Clouds continually passing. The counting for I L. was 10' fast. (i) 'A brighter in the south-following quarter.' (j) 'The following and fainter of two near each other.' (The other is Bessel xiii. 444). 'Both preceded by a star of Mag. II and less N.P.D.' (l) Very faint. 'A star of Mag. 8.9 to the north of this.' (m) 'The north-following of two equal.' (n) Extremely faint. (o) Note of the observer, 'Query if 15' fast.' The observation has been diminished 5" to agree with one taken June 13, 1849.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,337, -26°,913, -13°,618, +0°,060, +13°,573, +26°,892, +40°,344.

(a) 'A brighter of less N.P.D. follows.' (b) Bad definition. (c) Extremely faint: no object near this. (d) Faint. Clouds had just cleared off; In estimating the clock-rate for this day B is assumed to observe earlier than T by 0,2. (e) Faint: about Mag. 9½. (f) Too cloudy for I L: this partly without the dark glass. (g) 'One brighter of nearly the same R.A. lower in the field.' See May 19. (h) 'A fainter south following.' (i) Extremely faint: the sky very misty. (k) Could not be observed with any certainty. (l) Unsteady. (m) Cloudy. (n) Rather faint from haze. (o) Very steady. (p) 'Good.' (q) Clouds passing.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',337, -26',913, -13',618, +0',060, +13',573, +26',892, +40',344.

June 19, 8^h, just before the observation of Arcturus, Hardy was put forward 1^m.

(a) Very steady: the evening cloudy. (b) Much obscured by cloud. (c) Great motion. (d) Cloudy. (e) The other Limb was hid by cloud.
 (f) 'Good.' (g) Bad definition. (h) Clouds passing. (i) Satisfactorily observed, though faint. (k) Partly without the dark glass: 1 L. quite hid.
 The noted times have been increased 2". (l) Very faint. (m) Wire III was set down 8,8 and altered at the time. (n) 'A fainter of somewhat greater N.P.D. precedes.' (o) 'Higher in the field than Antares.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.	Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s.337$, $-26^s.913$, $-13^s.618$, $+0^s.060$, $+13^s.573$, $+26^s.892$, $+40^s.344$.

(a) The counting was 1^s slow. (b) Cloudy. (c) Faint from cloud. (d) 'A fainter object preceded 15^s.' (e) Extremely unsteady. (f) Could scarcely be observed, so badly defined.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°,337, - 26°,913, - 13°,618, + 0°,060, + 13°,573 + 26°,892, + 40°,344.

(a) 'One brighter of less N.P.D. following.' (b) 'A brighter follows higher in the field.' (c) Blazing. (d) The change of clock-error since June 28 is, I think, owing to the minute-hand catching against the hour-hand. The adopted rate of June 30 is uncertain. (e) The noted times have been increased 1^m. (f) Cloudy. (g) In calculating the mean clock-error weights are given to these observations proportional to the respective number of wires. (h) Partly without the dark glass. (i) 'Preceding' 25 Scorpii and of less N.P.D. (k) Cloudy at times. (l) Clouds passing. (m) Bad definition. (n) 'One follows lower in the field.'

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40^s.337, -26^s.913, -13^s.618, +0^s.060, +13^s.573, +26^s.892, +40^s.344.

(a) Wire VII has been increased 1^s conjecturally. (b) Bright, but clouds passing. (c) Wires VI and VII have been diminished 1^s from a consideration of the intervals. The observer thought that a second was lost. (d) Bright. (e) Bad definition. (f) 'Two fainter preceded about 1m.' (g) The noted times were 1^s greater. The counting was found to be 1^s fast, but the observer was doubtful whether the error applied to the observation. (h) Observed by mistake for h¹ Sagittarii. (i) Cloudy. (k) Faint.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.	Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40,337, -26,913, -13,618, +0,060, +13,573, +26,892, +40,344.

(a) Extremely unsteady. (b) The times have been diminished 1^s conjecturally. (c) Could not be seen with any of the dark glasses and too dazzling without: the observation was very uncertain. (d) Partly without the dark glass, but too dazzling. (e) Very faint from cloud. (f) Cloudy. (g) Very faint at times. (h) Extremely faint: wire IV very doubtful. (i) Tremor. (k) Temp. 69,0: 2 L. clouded. (l) Wire VII doubtful. (m) Temp. 62,6. (n) Much obscured by cloud: partly without the dark glass. Temp. 62,5. (o) Difficult to observe on account of clouds: wire V for each L. marked doubtful. Temp. 62,1. (p) Temp. 65,1. (q) Badly illumined field. Wire III was set down, 0,2. (r) A brighter of greater N.P.D. followed about 14^s. (s) Not seen till after wire I, clouded at wire VII. (t) Hurried at wire I, which was set down 5,5, the seconds not being taken from the clock. Temp. 63,0. (u) Wire III marked doubtful: I was hurried in using a dark glass held in the hand, the attached glasses being out of order.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',337, -26',913, -13',618, +0',060, +13',573, +26',892, +40',344.

(a) Temp. 66° 0. (b) Wires IV and V were set down 51,5 and 5,2: counting corrected by looking at the clock. (c) Great waving. Temp. 65° 0. (d) Temp. 68° 0. (e) Tremor. Wire III was set down 23,4. (f) Wire IV doubtful from cloud. (g) Not good: the observer fatigued. (h) In calculating the clock-rates from observations of C and T, no allowance is made for difference of personal equation, which appears to be very small. See Introduction. (i) 'Good observation.' (k) The counting was 10' fast after wire I. (l) Tremor. (m) Cloudy. (n) Temp. 66° 2. (o) Often hid by cloud. (p) Bad definition. (q) Great unsteadiness. (r) Very faint from thin cloud. Temp. 59° 0. (s) Vibrating. (t) Observed at first hurriedly: not placed till after wire III between the horizontal wires. (u) I was confused by wrong setting: wires III and V were set down 52,3 and 8,4, neither being taken from the clock, and the counting for wires VI and VII was found to be 3' slow. (v) Bad illumination. Wire II was set down hurriedly 10,4, the seconds not being taken from the clock. (y) Unsteady. (z) Observed confusedly, and at first not well in focus. (aa) Good.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40",337, - 26",913, - 13",618, + 0",060, + 13",573, + 26",892, + 40",344. Aug. 24, 21^h, Hardy was put forward 1^m.

(a) Cloudy. (b) Faint. (c) Great motion. (d) Temp. 66°.3. (e) Temp. 69°.3. (f) Eunomia coming shortly after this was accidentally missed. (g) The first four wires not taken from the clock; the counting for the rest was found to be 1^s fast. (h) The times are corrected by + 0",04 for difference of personal equation. See Introduction. (i) Wire VII was set down confusedly 59,7. (k) Observed doubtfully: interruption by clouds. (l) So faint that tenths of seconds could only be guessed at. Wire IV was set down confusedly 7,3, and the counting was found to be 20^s slow. (m) Temp. 66°.5. (n) Wire VI doubtful from cloud, wire VII from disturbance. (o) Bad definition and clouds passing. (p) Taken respectively at - 3^s, - 2^s, - 1^s, + 6^s, + 7^s, + 8^s from the middle wire. The reduction to the middle wire, as deduced from the first and last = - 1^m, 50",91. The interruption by cloud. (q) Unsteady and flaring. (r) The observations marked B, were taken by Mr John William Breen. The adopted rates are deduced from C's observations. (s) Faint from cloud. (t) Too short an interval after the preceding observation: wire 1 doubtful, and the counting 2^s slow.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s,337$, $-26^s,913$, $-13^s,618$, $+0^s,060$, $+13^s,573$, $+26^s,892$, $+40^s,344$.

(a) Not good: wire V was set down 17.7. Grouped with C's observations of Aug. 28. (b) The correction $+0^s,02$ is applied to B's observations for difference of personal equation of C and B. See Introduction. (c) Very faint. (d) Flaring. Temp. 53°F . (e) Cloudy. (f) The limb unusually ragged: could not be observed accurately. (g) Wire VI doubtful from cloud. (h) The observations of C and B on this day are reduced independently, the rate being inferred exclusively from C's observations. C's mean loss of clock at 0^h exceeds B's by $0^s,06$. (i) Very faint from day-light. (k) Probably the Planet. (l) Cloudy after this.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s,337$, $-26^s,913$, $-13^s,618$, $+0^s,060$, $+13^s,573$, $+26^s,892$, $+40^s,344$.

(a) Observed very unsatisfactorily. (b) Wire III was set down confusedly 27,9 for 28,1. (c) Grouped with B's observations of Sept. 3. (d) Observed with difficulty, clouds scarcely allowing a dark glass to be used. Wire I of 1 L. was taken hurriedly, and 1^s was lost after wire II, which has been supplied. Temp. 58° 2. (e) Clouds. (f) No allowance made for difference of personal equation of C and T. (g) Grouped with the observations of the preceding night. (h) Disturbance by noise. (i) The counting 1^s fast: all the wires except I have been diminished 1^s. (k) All the wires have been diminished 2^s. (l) The counting for all the wires after II was 10^s short. (m) Complete disturbance by noise. (n) Bad definition. (o) Cloud at wire I: mostly without the dark glass. (p) Great motion: interruption by cloud after wire IV. (q) Extremely unsteady. (r) So unsteady as to make some wires quite doubtful. (s) Very unsteady: not seen earlier. (t) Very faint.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40', 337, - 26', 913, - 13', 618, + 0', 060, + 13', 573, + 26', 892, + 40', 344.

(a) A fainter object preceded about 35". (b) Observed for Hygiea. (c) 'Unsatisfactory observation.' (d) Counting 20" fast for the last four wires.
 (e) This observation proved that the object observed Sept. 11 was not the Planet. The Ephemeris was in fault. (f) Extremely unsteady at some wires.
 (g) Very faint and tremulous. (h) The observations of C and T on this day are reduced independently: T's mean loss of clock at 0^h is greater than C's by 0', 15. The rate is inferred from T's observations. (i) 'The first and most northern of three.' (k) 'One equal south-following,' viz. B.A.C. 6727.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',337, -26',913, -13',618, +0',060, +13',573, +26',892, +40',344.

(a) Faint. (b) Disturbance by noise in the court. (c) Extremely unsteady. (d) The counting was 2^s fast: correction applied. (e) Bad definition. (f) Diffused and unsteady. (g) Great motion. The noted times for 1 L. were 29^s greater. (h) Very faint from cloud. (i) Faint and unsteady. (k) Greatly diffused. The last four wires have been diminished 10^s. (l) Unsteadiness and interruption by clouds: all the wires except VII of 2 L. without the dark glass. (m) Great motion. (n) Cloudy: partly without the dark glass. In calculating the rate for this day B is assumed to observe earlier than T by 0,2.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,337, -26°,913, -13°,618, +0°,060, +13°,573, +26°,892, +40°,314.

(a) Cloudy. (b) 'Another precedes.' (c) 'A very faint object precedes.' The preceding object, a transit of which was taken at wire II, is the Planet. The star was observed with the Circle on the same day. (d) Partly without the dark glass. (e) Not seen before (at 3^h). (f) 'Of a bright crimson and yellow colour.' (g) 'The preceding of two.' (h) 'The following of two.' (i) 'Three others follow.' (j) 'Of Mag. 11.' Another object following a very little and of greater N.P.D. was also observed. (k) 'Others following.' (l) 'Cumuli clouds passing.' (m) 'Cumuli clouds passing.' (n) 'Faint from cloud and bright moon-light.' (o) 'The counting was 4^s fast.' (p) 'Clouds passing.' (q) 'The np of a rather close double star,' viz. Σ 2928. (r) 'A brighter precedes about 18^s.'

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40',337, -26',913, -13',618, +0',060, +13',573, +26',892, +40',344.

Oct. 15, 9^h, Hardy was put forward 1^m. The rate seems to have changed in consequence.

(a) 'The north-preceding of two.' The other is Bessel xxiii. 104. (b) 'The north-following of two.' (c) 'Of Mag. 7.' (d) The observer thought this object too bright for the Planet. (e) Some very bright spots towards 2 L. were noticed. (f) Unsteady and disappearing at times. (g) Cloudy. (h) 'The following of two of the same Mag. and N.P.D.' (i) Very steady. (k) Partly without the dark glass. (l) Imperfect illumination of the field, and the star badly defined. (m) Very great motion and no definition. (n) Extremely faint. (o) Faint. (p) The observer was delayed at the Northumberland Dome. (q) Flaring.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, -40°,337, -26°,913, -13°,618, +0°,060, +13°,573, +26°,892, +40°,344.

Before the observation of Arcturus Nov. 10, Hardy was put forward 1^m.

(a) Cloudy. (b) Faint at times. (c) Cloudy. Without the dark glass, excepting some wires of 1 L. (d) 'A brighter of the same R.A. much lower in the field.' (e) 'Two preceded about 1^m, and one of less N.P.D. followed.' (f) Very faint. (g) The times set down were 6^s greater. (h) No clock-stars could be obtained. (i) Very bad definition. (k) The last three wires were each set down 30^s greater.

Month and Day.	NAME OF OBJECT.	Seconds of transit over the seven wires.							Concluded transit over the mean of the seven wires.	Correction of			Seconds of Meridian Transit.	Clock apparently Slow.	Adopted losing Rate.	Apparent R.A. from the Observation.			Observer.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40°,337, - 26°,913, - 13°,618, + 0°,060, + 13°,573, + 26°,892, + 40°,344.

(a) Badly defined and sometimes scarcely visible from cloud. (b) Quite clouded till wire VI. The counting was 17^s slow, and the times have been corrected accordingly. (c) Cloudy. (d) The times set down were 1^s greater. (e) Clouds passing. (f) Extremely faint. 'A bright object preceded and two fainter followed.' (g) 'A double star: several other objects.' The other component is Bessel i. 666. (h) Wires III and IV observed confusedly. (i) The noted times were 30^s less. (k) 'The south-preceding of a coarsely double star.' (l) 'A brighter of less N.P.D. followed a few seconds.' The following star is Bessel i. 981.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, - 40', 337, - 26', 913, - 13', 618, + 0', 060, + 13', 573, + 26', 892, + 40', 344.

(a) Extremely faint. (b) Faint. (c) The noted times have been increased 10". (d) 'Another followed.' (e) 'The south-preceding of a coarsely double star.' (f) The counting 1" fast. (g) Cloud. (h) Scarcely visible. (i) Corrected by - 20". (j) The clock almost inaudible from noise. (k) Extremely faint from cloud. Wire III was set down 48,2. (l) Flaring, and sometimes nearly hid by cloud. (m) Great motion. (n) Temp. 47°. (o) Very bad definition. (p) Extremely faint: seen only at these wires. (q) Very ragged. (r) Steady, but faint from cloud. (s) Very faint, the sky being overcast. (t) The counting was 1" slow. (u) Not seen before, so faint from day-light.

ILLUMINATION WEST. INTERVALS for an Equatorial star from wires I, II, III, IV, V, VI, VII, to the mean of the seven wires, $-40^s,337$, $-26^s,913$, $-13^s,618$, $+0^s,060$, $+13^s,573$, $+26^s,892$, $+40^s,344$.

(a) 'Another of Mag. 8.9 of the same R.A. and less N.P.D. by about 4'.' (b) The counting was 1^s fast: correction applied accordingly. (c) Very faint.
 (d) Flaring. (e) Bad definition. (f) Very irregular motion. (g) The illumination failing. (h) Faint from cloud. (i) The first four wires lost by the noise of a carriage passing. (k) The observer was delayed at the Northumberland Dome.

MEAN RIGHT ASCENSIONS, JANUARY 1, 1851,

OF THE

FUNDAMENTAL STARS

OBSERVED IN THE YEAR 1851,

AS DEDUCED FROM EACH DAY'S OBSERVATION.

Nos. 2 and 3. The magnitudes were noted in Transit observations of these stars on Nov. 19, 1856.

No. 21. The accompanying star, Bessel I. 666, was considered to be of Mag. 8 $\frac{1}{2}$.

Nos. 25 and 26. Mistaken for Bessel I. 750 through an error in the working Catalogue. The N.P.D. was obtained by a Circle observation 1851, Nov. 25.

No. 29. There must have been a mistake in counting. Bessel's R.A., which is 4 s greater, has since been confirmed.

No. 34. The accompanying star was considered to be of Mag. 10. See the note to the observation.

No. 40. Bessel's R.A. is about 1 s greater.

No. 61. The R.A. is 1 s greater than that of H. C., but agrees with that of Bessel z. 393, 3 h . 47 m . 49 s , which is the same star.

The accompanying star, H. C. 7263, was considered to be of Mag. 8 $\frac{1}{2}$.

No. 67. Bessel IV. 103 was judged to be of the same magnitude.

No. 425. This is B.A.C. 5281, the R.A. of which is 20s greater, by an error in reducing from the H. C.

No. 434. The R.A. of B.A.C. is 1s greater, and is the same as that of ν Scorpii. See the note to the observation.

Nos. 453 and 454. Lacaille's R.A. is about 4s greater.

No. 479. Not used for the concluded R.A. See the transit.

ONE REVOLUTION of the MICROMETER = 20".841. ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.
 ASSUMED CO-LATITUDE = 37°.47'.8".00.

(a) Slip of Circle, bisection repeated. (b) Extremely faint from cloud. (c) Negative correction for Runs. (d) Unsteady. (e) Faint from cloud: the observation doubtful. (f) Very steady. (g) The correction for Runs is assumed to be negative: no note was made. (h) Cloudy and the mercury unsteady. (i) Dense cloud: very doubtful observation. (k) Further observation interrupted by cloud. (l) Waving. (m) Blazing. (n) The mercury very tremulous. (o) Faint: the sky misty. (p) Faint and cloudy. The Limb was full, but very uneven; the extreme illuminated point was bisected.

ONE REVOLUTION of the MICROMETER = 20".841. ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8".00.

(a) Negative correction for Runa. (b) Too much wind. (c) The mercury much disturbed. (d) Taken by mistake for H. C. 9517.
 (e) 'Satisfactory observation.' (f) The observer, mistaking the time, was too late to prepare for observing both limbs. (g) 'The south-preceding taken.' The other is H. C. 14394. (h) 'Good.' (i) Badly defined. (k) No definition: the night unfavorable. (l) 'Not good.'
 (m) 'A brighter star of less N.P.D. preceded.' (n) The pointer reading has been diminished 5'.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Cloudy. (b) Negative correction for Runs. (c) Clouded and badly defined. (d) Very faint. (e) Very faint from cloud. (f) The Circle dripping with moisture. (g) Very badly defined and extremely unsteady. (h) 'Preceded the next about 15'. (i) The micrometer reading was set down 15",812. The alteration was made from a comparison of this with a later observation.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16',6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Negative correction for Run. (b) A large and unsteady image. (c) Observed hurriedly. (d) Cloudy. (e) 'The bisection made hurriedly: it appeared best at half an interval from the middle wire.' Correction applied accordingly. (f) Unsatisfactory: the mercury waving. (g) Times by Molyneux, 6^h. 23^m. 10^s and 6^h. 26^m. 56^s. Molyneux fast, 1^m. 54^s. (h) Too unsteady for a good bisection. (i) Clouded: without the dark glass. (k) The mercury disturbed by wind. (l) 'The north-following of two of equal magnitude.' (m) Observed hurriedly.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6. ASSUMED CO-LATITUDE = 37°. 47'. 0",00.

March 1, The Circle was taken from the wall and the pivots were cleaned and oiled.

March 3, the Microscopes were made to point to the middle of the gold band, and their readings were adjusted. The micrometer wire was found to be equatorially adjusted.

(a) Negative correction for Runs. (b) Very cloudy; doubtful observation. (c) Badly defined and faint from cloud. (d) Time by Molyneux, 6h. 25m. 0s and 6h. 26m. 11s. Molyneux fast, 2m. 16s. (e) Cloudy. (f) The mercury unsteady. (g) 'The northern and brighter of a course double star.' (h) 'One equal north-following.' (i) 'A brighter south-following.' (k) 'One equal south-preceding.' (l) 'Good.' (m) Without the dark glass: not satisfactory.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°.47'.8",00.

(a) Negative correction for Runs. (b) Flaring. (c) The Zenith Point had been taken on March 2, before the microscopes were adjusted. (d) Just clear of clouds. (e) Observed doubtfully, so faint. 'A brighter south-follows.' (f) Too faint. (g) 'A fainter north-preceding, and a brighter south-preceding.' This appears to be the Planet. (h) 'Another of less N.P.D. and the same magnitude was in the field.' (i) The wire was placed mid-way between the stars.

ONE REVOLUTION of the MICROMETER = 20".841. ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.
 ASSUMED Co-LATITUDE = 37°. 47'. 8".00.

(a) The microscope readings were 1' less. See the observations of this star May 9 and May 14. (b) Very doubtful observation, the limbs being nearly invisible from dense cloud. (c) The evening cloudy. (d) Not good: the star very faint. (e) Uneven: a slight projection from the limb was bisected. (f) Very tremulous. (g) Negative correction for Runs. (h) Cloudy. (i) 'The southern and fainter of two.' (k) 'The preceding star.' (l) The R.A. was determined by an equatorial observation on April 2, 1857. (m) The mean of these is the adopted Zenith Point. (n) Steady. (o) Times by Molyneux, 1^h. 4^m. 4^s, 1^h. 5^m. 33^s, 1^h. 13^m. 47^s and 1^h. 14^m. 54^s. Molyneux fast on Hardy, 59". (p) The other limb hid by cloud. (q) Two very faint stars preceded. (r) The instrument was set for Bessel XII. 694, which could not be seen. This star was low in the field.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Negative correction for Runs. (b) 'Another precedes.' (c) 'No star seen in the place of H. C. 23583. (d) Seen but for a second; very cloudy. (e) Extremely faint from cloud. (f) Delay caused by cloud. (g) Without the dark glass and very faint. (h) 'Two faint stars of nearly the same N.P.D. preceded about an interval.' See April 28. (i) The micrometer reading was entered 26,131, after turning the micrometer head. The observer doubted whether it should not be 26,531, which appears to be the correct reading. (k) Cloudy. (l) 'Not good.' (m) 'Two stars of the same R.A.' The other is Bessel XII. 93. (n) 'Two stars of Mag. 10½ precede.' (o) The Circle reading was 1' less. See the observations of May 13, 15 and 19. (p) Times of bisection by Molyneux, 13^h. 4^m. 31^s, 13^h. 5^m. 27^s, 13^h. 11^m. 25^s and 13^h. 12^m. 10^s. Molyneux fast on Hardy, 1^m. 37^s. (q) 'Good.' (r) Wrong setting; the direct observation was considered good.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refrac- tion.	Apparent N.P.D. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°.47'.8",00.

(a) 'Follows the preceding about 25" and is brighter.' (b) Very faint. (c) 'At least of Mag. 9.' (d) Negative correction for Runs.
 (e) Times by Molyneux, 12^h.59^m.14^s, 13^h.4^m.22^s, 13^h.9^m.37^s and 13^h.15^m.16^s. Molyneux fast on Hardy, 2^m.10^s. These observations were used for calculating the value of the micrometer revolution. (f) Extremely faint. (g) 'One of Mag. 9 south-following.' (h) Not observed to be double. (i) Cloudy: the star barely visible at the direct observation. The sky had been thick all the evening. (k) 'Good observation.' (l) The other Limb lost by wrong setting. (m) 'Pretty good.' (n) Cloudy. The circle reading for N.L. has been increased 1". (o) Quite alone, and very faint. After this the sky was clouded.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Taken very doubtfully without the dark glass. (b) Negative correction for Runs. (c) Extremely faint: the observation doubtful. (d) 'A fainter north-following a few seconds.' (e) A third star north following these was noticed. (f) Very faint, but the bisection considered good. (g) 'A double star and another of equal magnitude preceding.' (h) The star noticed June 17. (i) The direct observation lost by wrong setting. (k) 'An object of equal magnitude north preceding by 11s.' (l) The Planet very faint and observed hurriedly. (m) Faint from cloud. (n) Extremely faint. (o) Too unsteady for good observation.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Run for 5'.	Micrometer Readings.	Interval from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refraction.	Apparent N.P.D. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Extremely unsteady and badly defined.
 south-following. The R.A. is approximate.

(b) Negative correction for Run.
 (d) Unsteady. (e) Great motion.

(c) Doubtful observation. 'A brighter north-preceding and another
 (f) 'A brighter north-preceding.'

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refraction.	Apparent N.P.D. from the Observation.	Observer.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED Co-LATITUDE = 37°. 47'. 8",00.

(a) Cloudy: N.L. observed better than S.L. (b) Unsteadiness and bad definition. (c) Faint but steady. (d) Much clouded: bisected doubtfully without the dark glass. (e) Negative correction for Runs. (f) Rather rugged. (g) Doubtful observation, the star being very faint. (h) Immediately after the bisection the Sun was hid by cloud.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) 'One of equal Mag. north-following.' (b) Very faint. (c) 'A coarse double-star precedes.' (d) Negative correction for Runs. (e) 'Precedes the next about an interval.' (f) Bright. (g) Very faint; Mag. 11. (h) Extremely bad definition and fog sweeping over the sky: the observation scarcely to be depended upon. (i) Unsteadiness and bad definition. (k) 'Objects following this.' (l) 'Of the same R.A.' (m) 'Follows the preceding by two intervals.' (n) 'This follows by about 7s.' (o) 'One of greater N.P.D. preceded a few seconds.' (p) 'The R.A. is roughly approximate.' (q) Bright and well observed. (r) Clouded, but the observation not doubtful.

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refraction.	Apparent N.P.D. from the Observation.			Observer.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Bad definition and unsteadiness. By accident the micrometer reading was 10",000. (b) Faint. (c) The reflection observation good, the other doubtful from cloud. (d) 'Mag. 7.8.' (e) Cloudy. (f) Very faint and bisected hurriedly after passing the comb, being clouded before. (g) Boiling motion and cloud. Without the dark glass. (h) Doubtfully bisected, so faint from cloud. (i) Very cloudy. (k) Negative correction for Runs.

ONE REVOLUTION of the MICROMETER = 20'',841. ONE INTERVAL from the middle wire for an Equatorial Star = 16'',6. ASSUMED CO-LATITUDE = 37°. 47'. 30''.00.

Oct. 9, 0^h, the Circle was taken from the pier and its axis cleaned. The microscopes were then adjusted and the Zenith Point was taken.

(a) Extremely faint from cloud. (b) 'Good observation.' (c) Bisected hurriedly beyond the comb. (d) 'A fainter object south-following.' The circle reading has been diminished 10' conjecturally. (e) Interruption by clouds: both limbs bisected hurriedly, especially N.L. (f) These objects all very faint from cloud, and the bisections more or less doubtful. (g) No star near this: a brighter noticed at the top of the field. (h) Negative correction for Runs. (i) 'The preceding of two a few seconds apart, and of nearly the same N.P.D.' (k) This Zenith Point is not used. (l) Taken at 23^h. On reading the microscopes for Runs soon after, a discordance was noticed in the reading of microscope E, which appears to have continued through Oct. 10. This Zenith Point is therefore not used till Oct. 11. (m) Used only on Oct. 10. The wires of microscope E were probably disarranged by pushing in the eye-piece too far. (n) Extremely faint. The circle readings unsatisfactory this night on account of moisture on the circle and eye-pieces.

ONE REVOLUTION of the MICROMETER = 20".841. ONE INTERVAL from the middle wire for an Equatorial Star = 16".6.
 ASSUMED CO-LATITUDE = 37°.47'.8".00.

(a) Negative correction for Runs. (b) See Oct. 9. (c) Very cloudy. (d) Doubtful observation on account of cloud. (e) No object in the neighbourhood of this. (f) N.L. lost by cloud. (g) Between the observations of Oct. 17 and Oct. 22 microscope E was repaired. (h) Taken Oct. 22, 21^h–22^h. (i) Very cloudy, and the star badly defined. (k) 'Mag. 10.' (l) Extremely faint. (m) 'Not observed to be double: a fainter object followed.' (n) The mercury very much disturbed by wind, and the bisection quite uncertain.

ONE REVOLUTION of the MICROMETER = 20",841. ONE INTERVAL from the middle wire for an Equatorial Star = 16",6.
 ASSUMED CO-LATITUDE = 37°. 47'. 8",00.

(a) Negative correction for Runs. (b) Not seen earlier: the eye-piece misty and bisection doubtful. (c) Doubtful from cloud: the night unfavorable for observing. (d) A brighter object of somewhat less N.P.D. was noticed. (e) Beautifully steady. (f) Bisected by T. (g) Faint. Mist on the eye-piece. (h) Too faint to bisect with certainty. (i) 'North-following a bright star.' (k) Mistaken for Bessel ι . 750 through error in the working catalogue. (l) Blazing. (m) 'One of equal magnitude preceded high in the field.' (n) A preceding and fainter object was also bisected. (o) 'A fainter north-preceding.'

Month and Day.	NAME OF OBJECT.	Microscope Readings.						Correction for Runs for 5'.	Micrometer Reading.	Intervals from the middle wire.	Concluded Circle reading.	Barom.	Thermom.		Refraction.	Apparent N.P.D. from the Observation.	Observer.

HORIZONTAL AND VERTICAL MEASURES
OF THE
DIAMETERS OF THE SUN AND MOON,
COMPARED WITH TABULAR DIAMETERS:
AND
RIGHT ASCENSIONS AND NORTH POLAR DISTANCES
OF THE SUN AND MOON,
AND THE PLANETS METIS, IRIS, HEBE, PARTHENOPE, ASTRÆA,
IRENE, EUNOMIA, HYGEIA AND NEPTUNE,
CONCLUDED FROM
OBSERVATIONS WITH THE TRANSIT AND MURAL CIRCLE,
AND COMPARED
WITH CALCULATED RIGHT ASCENSIONS AND NORTH POLAR DISTANCES.

1851.

SIDEREAL INTERVALS OCCUPIED BY TRANSITS OF THE SUN'S DIAMETER, AND VERTICAL
DIAMETERS OF THE SUN CORRECTED FOR REFRACTION AND PARALLAX; COMPARED
WITH THE VALUES IN THE NAUTICAL ALMANAC.

Day of Observation.	Interval by Obser- vation.	Seconds of Tabular Interval.	Excess of Tabular Interval.	Vertical Diameter by Observation.	Seconds of Tabular Diameter.	Excess of Tabular Diam ^r . April 17. The observation very uncertain.

Sept 17. The observed vertical diameter altogether discordant. See the note to the observation.

Feb. 1. The correction +0,20 was applied to B's observation for difference of personal equation of B and T.

April 23, April 24, May 7, June 14, July 3, and Oct. 22. No accompanying Clock-stars.

May 23. The circle observation as recorded was 1' in error.

The Tabular Errors in brackets are not used in the calculation of the position of the Ecliptic, that of March 11 being rejected to reduce the Circle observations of single Limbs to an even number, and the rest being considered too discordant.

The corrections applied for defect of Illumination are +0°.02 to 2 L. on Feb. 15, +0°.10 to 2 L. on May 14, +0°.14 to 2 L. and -0°.03 to N.L. on July 12, and -0°.22 to 1 L. on Dec. 8. The S.L. was ascertained by calculation to be full on April 17.

Jan. 14. The observation was very doubtful.

July 2. At three wires under bad circumstances: perhaps an error of 1° in the observation.

Aug. 20. See the note to the Circle observation.

18. 11. 27. 35,6	7	19. 12. 39,02	37,93	- 1,09	5,90	100. 7. 59,15	54,36	- 4,79
21. 11. 12. 56,9	7	19. 9. 47,59	46,56	- 1,03	5,93	100. 36. 2,14	58,35	- 3,79

June 30. The rate of the clock was doubtful.

The object observed for Hebe with the Transit on Sept. 3 was proved by calculation not to be the Planet.

RIGHT ASCENSIONS AND NORTH POLAR DISTANCES OF PARTHENOPE.

Oct. 8. 12. 58. 34,2	5	2. 7. 10,00	18,11	+ 8,11				
10. 12. 49. 3,0	4	2. 5. 30,30	38,57	+ 8,27				
15. 12. 25. 2,0	5	2. 1. 8,09	16,07	+ 7,98				
16. 12. 20. 12,0	5	2. 0. 13,90	21,78	+ 7,88	4,70	86. 9. 7,58	51,60	- 15,98

26. 9. 9. 26,9	7	1. 30. 36,17	41,26	+ 5,09	4,19	88. 4. 3,20	45,99	(- 17,21)
Dec. 11. 8. 9. 15,2	2	1. 29. 22,94	28,06	+ 5,12	3,76	87. 28. 40,12	31,75	- 8,37

Nov. 24. Some doubt about the micrometer reading, which was written down 10,493 and altered conjecturally to 10,293, being supposed to be the same as the preceding reading for Iris.

Nov. 26. The other object was supposed to be the Planet. See the Note to the Circle observation.

RIGHT ASCENSIONS AND NORTH POLAR DISTANCES OF ASTRÆA.

Apr. 19. 12. 52. 55,3	7	14. 43. 22,62	28,44	+ 5,82	5,15	96. 42. 14,58	39,89	+ 25,31

Oct. 2. At three wires under bad circumstances.

Nov. 4. See the Note to the Circle observation.

Dec. 19. The Planet was at this time observed with difficulty.

DETERMINATION OF THE POSITION OF THE ECLIPTIC, AND OF THE MEAN ERROR OF
THE ASSUMED RIGHT ASCENSIONS OF THE FUNDAMENTAL STARS, FROM THE
TRANSIT AND CIRCLE OBSERVATIONS OF THE SUN IN THE YEAR 1851.

The total number of Circle Observations of the Sun, in which both Limbs were observed, was 118, those of April 17 and Sept. 17 being excluded; and the number of observations of single Limbs, exclusive of those of March 11 and Aug. 6, was 14. The observations of single Limbs are taken into account, half-weight being given to each. The whole are divided into four groups containing $31\frac{1}{2}$, 30, $31\frac{1}{2}$ and 30 observations. Each of these is subdivided into three groups, as exhibited in the subjoined Table. This Table contains also the limiting days and the mean day of each group, the mean value (α) of the Tabular Errors in North Polar Distance, derived from the columns in pages 405—407, and the Sun's Longitude (λ) and North Polar Distance (Δ) at the mean noon of the mean day.

Limiting Days of Observation of each group.	Mean Day.	Mean of the Tabular Errors in N.P.D.	Number of Observations.	Sun's Longitude at mean Noon of mean Day.	Sun's N.P.D. at mean Noon of mean Day.

Formula of Calculation.

$$\alpha + m \operatorname{cosec} \lambda \operatorname{cosec} \Delta + n \sin \lambda \operatorname{cosec} \Delta + p = 0.$$

The following equations were formed according to this formula by means of the data in the Table above, each equation being multiplied by the respective number of observations.

$$\begin{aligned}
 \text{First Quarter} & \left\{ \begin{array}{l} \text{Jan. 18.....} - 1,78 + m \times 5,2435 - n \times 9,9166 + 10,5p = 0. \\ \text{Feb. 10.....} + 4,84 + m \times 8,8539 - n \times 7,1155 + 11p = 0. \\ \text{Mar. 3.....} + 8,60 + m \times 9,5995 - n \times 3,0542 + 10p = 0. \end{array} \right. \\
 \text{Second Quarter} & \left\{ \begin{array}{l} \text{Apr. 18.....} + 3,47 + m \times 9,4491 + n \times 4,9912 + 10,5p = 0. \\ \text{May 23.....} + 2,00 + m \times 5,3127 + n \times 9,8727 + 10,5p = 0. \\ \text{June 20.....} - 8,30 + m \times 0,2852 + n \times 10,8964 + 10p = 0. \end{array} \right. \\
 \text{Third Quarter} & \left\{ \begin{array}{l} \text{July 14.....} - 22,66 - m \times 4,3187 + n \times 11,0282 + 11p = 0. \\ \text{Aug. 14.....} - 20,16 - m \times 8,4338 + n \times 6,8182 + 10,5p = 0. \\ \text{Sept. 12.....} - 16,10 - m \times 9,8474 + n \times 1,8971 + 10p = 0. \end{array} \right. \\
 \text{Fourth Quarter} & \left\{ \begin{array}{l} \text{Oct. 19.....} - 19,01 - m \times 9,6185 - n \times 4,5905 + 10,5p = 0. \\ \text{Nov. 12.....} - 14,81 - m \times 7,1495 - n \times 8,3827 + 10,5p = 0. \\ \text{Dec. 3.....} - 4,20 - m \times 3,5524 - n \times 10,1899 + 10p = 0. \end{array} \right.
 \end{aligned}$$

New equations were formed from the above by adding and subtracting as here indicated :

$$\text{First Quarter} + \text{Second} + \text{Third} + \text{Fourth.....} - 88'',11 - m \times 4,1764 + n \times 2,2544 + 125p = 0.$$

$$\text{First Quarter} + \text{Second} - \text{Third} - \text{Fourth.....} + 105'',77 + m \times 81,6642 + n \times 9,0936 = 0.$$

$$\text{First Quarter} - \text{Second} - \text{Third} + \text{Fourth.....} + 35'',39 + m \times 10,9294 - n \times 88,7532 = 0.$$

The solution of these equations gives,

$$m = - 1'',321,$$

$$n = + 0'',236,$$

$$p = 0'',656.$$

Let $\delta\lambda$ = the mean excess for the year of the Tabular Longitude of the Sun above the true Longitude.

δR = the mean excess for the year of the Tabular R.A. of the Sun above the true R.A.

$\delta\Delta$ = the mean excess for the year of the Tabular N.P.D. of the Sun above the true N.P.D.

δI = the mean excess of the Obliquity (I) assumed in the Tables above the true Obliquity.

$A = -0^s,146$, which is the mean of 133 apparent excesses of the Tabular R.A. in pages 405—407, those of Sept. 17 and Oct. 22 being excluded, and half-weight being given to the results of observations of single limbs.

$D = -0'',705$, which is the mean of the 132 apparent excesses of Tabular N.P.D. used in forming the foregoing equations, half-weight being given to observations of single limbs.

q = the mean excess of the assumed R.A. of the fundamental stars above the true R.A.

p = the mean excess within the Tropics of the N.P.D. determined by the Circle observations and calculations of 1851 above the true N.P.D.

Then, $\delta\lambda = m \operatorname{cosec} I = -1'',321 \times \operatorname{cosec} 23^\circ.27',5 = -3'',319$.

$$\delta R = \frac{\delta\lambda}{15} \times \frac{\Sigma \cos I \operatorname{cosec}^2 \Delta}{2\pi} = \frac{\delta\lambda}{15} \text{ nearly} = -0^s,221.$$

$$\delta\Delta = (\text{Tabular N.P.D.} - \text{Observed N.P.D.}) + (\text{Observed N.P.D.} - \text{True N.P.D.})$$

$$= D + p = -0'',705 + 0'',656 = -0'',049.$$

$$\delta I = n \sec I = +0'',236 \times \sec 23^\circ.27',5 = +0'',257.$$

$$q = (\text{Tabular R.A.} - \text{True R.A.}) - (\text{Tabular R.A.} - \text{Observed R.A.})$$

$$= \delta R - A = -0^s,221 + 0^s,146 = -0^s,075.$$

Hence the assumed R.A. of the fundamental stars are too small by the mean quantity $0^s,075$.

OCCULTATIONS
OF
FIXED STARS BY THE MOON,
WITH
THE EQUATIONS GIVEN BY THE CALCULATION
OF THE OCCULTATIONS.

1851.

COMPARISONS OF CHRONOMETERS WITH THE TRANSIT CLOCK, USED IN THE
CALCULATION OF THE FOLLOWING OCCULTATIONS.

* * THE letter *H* is an abbreviation for Hardy, the Transit Clock. *U* and *X* are Sidereal Chronometers, each beating half-seconds.

(a) 'True to the tenth of a second. The wind being high, the counting was checked after the observation. The sky was clear, but the star somewhat ill-defined and dancing.' (B). 'Good I think.' (T). (b) The Moon low and the star very faint from thick cloud: the observation was considered to be accurate to half a second. (c) 'Exact to one-tenth of a second I think. The star was bright and the sky clear.' (d) 'Beautifully exact: the Limb of the Moon could be seen quite round, but I did not observe any projection of the star on the Limb.' (B). Good: the star disappeared instantaneously.' (T). The time recorded by B was 1^m later. (e) 'As exact as the time of disappearance.' (B). 'May be late, as I used a low power.' (T). (f) Both observations considered very exact. (g) 'At the noted time I saw what appeared to be the star on the Moon's Limb, and χ^1 Orionis was well seen north-preceding: but there was so much cloud that I could not be sure. The Moon was low and waving.' The calculation of this observation, which shewed that the noted time was considerably too late, is not added. (h) 'Very good: the Limb was seen all round.' (i) 'Very exact: the Moon's Limb was tremulous.' The seconds were counted by T. (k) 'The Moon's edge was unsteady, but the time was quite exact.' (B). 'Good.' (T). The time of disappearance at a bright Limb is likely to be more exact with the Northumberland Telescope than with that of the 5-feet Equatorial. (l) 'Very good: seen instantly I think.' (B). 'Not seen soon enough, looked for in a wrong place.' (T). (m) 'Clouds sweeping over the Moon, and the star disappearing and reappearing, but occasionally very bright.' (n) Clouds over the Moon and the star faint, but the time was considered exact. (o) 'Hurried observation: the right part of the Moon was looked at and the star was quite bright when first seen. I could not see the star when I first looked.' (p) The Moon steady, but the star very faint at last. The observation was considered good. (q) 'Seen at the instant of reappearance, the right place being looked at. The wind was blowing violently and shook the Telescope.' In this and other observations with the 46-inch Dollond, the tripod stand was placed in front of the Portico Door.

Disappearance of χ^3 Orionis, Jan. 15, $5^h.40^m.16^s.77 + t^s + \tau^s$ Greenwich Mean Solar Time.

Geocentric Colatitude of the Observatory	$37.58.20,37 + v$
Moon's apparent Right Ascension in arc	$70.56.8,93 + \delta R$
Moon's apparent N.P.D.	$71.19.3,26 + \delta \lambda$
Moon's apparent Semidiameter	$15.31,49 + \delta S$
Apparent Distance of Star from Moon's centre	$15.51,05 + \delta D$

$$\delta R = +0,4027t + 0,5600\tau + 1,0105x - 0,0008y + 0,4941m + 0,0031v$$

$$\delta \lambda = -0,1192t - 0,1083\tau + 0,0007x + 1,0136y + 1,8919m - 0,0137v$$

$$\delta S = +0,0001t + 0,9315n$$

$$\delta D = +0,8763\delta R - 0,8763e - 0,3799\delta \lambda + 0,3812f.$$

Final Equation:

$$-19'',56 = +0,8852x - 0,3858y - 0,8763e + 0,3812f + 0,3981t + 0,5319\tau + 0,0079v - 0,2858m - 0,9315n.$$

Disappearance of 63 Geminorum, Dec. 10, 12^h.30^m.54^s.84 + $t^s + \tau^s$ Greenwich Mean Solar Time.

Right Ascension of Zenith in arc	$86.57.15.60 + 15.0411 \times t$
Moon's Geocentric Right Ascension in arc	$109.13.0.15 + 0.6138 \times (t + \tau) + x''$
Moon's Geocentric N.P.D.	$67.40.58.25 + 0.0228 \times (t + \tau) + y$
Moon's Horizontal Parallax at the Observatory	$57.58.66 \times [9.9990916] \times (1 + 0.001 m)$
Moon's Geocentric Semidiameter	$15.47.95 \times (1 + 0.001 n)$
Star's Right Ascension in arc	$109.44.13.20 + e''$
Star's N.P.D.	$68.15.26.20 + f$
Geocentric Colatitude of the Observatory.....	$37.58.20.37 + \nu$
Moon's apparent Right Ascension in arc	$109.27.43.95 + \delta R$
Moon's apparent N.P.D.	$68.11.4.80 + \delta \lambda$
Moon's apparent Semidiameter	$16.1.27 + \delta S$
Apparent Distance of Star from Moon's centre .	$15.55.11 + \delta D$

$$\delta R = +0.4629t + 0.6202\tau + 1.0105x - 0.0018y + 0.8931m + 0.0056\nu$$

$$\delta \lambda = +0.0016t + 0.0241\tau + 0.0015x + 1.0140y + 1.8326m - 0.0144\nu$$

$$\delta S = +0.0003t + 0.9613n$$

$$\delta D = -0.8932\delta R + 0.8932e - 0.2728\delta \lambda + 0.2746f.$$

Final Equation :

$$+6''.16 = -0.9029x - 0.2751y + 0.8932e + 0.2746f - 0.4141t - 0.5605\tau - 0.0010\nu + 1.2976m - 0.9613n.$$

Reappearance of 63 Geminorum, Dec. 10, 13^h.44^m.31^s.53 + $t^s + \tau^s$ Greenwich Mean Solar Time.

Right Ascension of Zenith in arc	$105.24.27.30 + 15.0411 \times t$
Moon's Geocentric Right Ascension in arc	$109.58.11.55 + 0.6140 \times (t + \tau) + x''$
Moon's Geocentric N.P.D.	$67.42.45.47 + 0.0257 \times (t + \tau) + y$
Moon's Horizontal Parallax at the Observatory	$57.59.98 \times [9.9990916] \times (1 + 0.001 m)$
Moon's Geocentric Semidiameter	$15.48.32 \times (1 + 0.001 n)$
Star's Right Ascension in arc	$109.44.13.20 + e''$
Star's N.P.D.	$68.15.26.20 + f$
Geocentric Colatitude of the Observatory.....	$37.58.20.37 + \nu$
Moon's apparent Right Ascension in arc	$110.1.17.30 + \delta R$
Moon's apparent N.P.D.	$68.11.56.16 + \delta \lambda$
Moon's apparent Semidiameter	$16.2.32 + \delta S$
Apparent Distance of Star from Moon's centre .	$16.13.97 + \delta D$

$$\delta R = +0.4512t + 0.6209\tau + 1.0113x - 0.0004y + 0.1878m + 0.0012\nu$$

$$\delta \lambda = +0.0216t + 0.0263\tau + 0.0003x + 1.0147y + 1.7766m - 0.0148\nu$$

$$\delta S = +0.0001t + 0.9623n$$

$$\delta D = +0.9068\delta R - 0.9068e - 0.2148\delta \lambda + 0.2166f.$$

Final Equation :

$$-11''.65 = +0.9170x - 0.2183y - 0.9068e + 0.2166f + 0.4046t + 0.5574\tau + 0.0042\nu - 0.2112m - 0.9623n.$$
